I must disagree totally, and for reasons you will find echoed on that
URL I gave.

Our material bodies are as if they are constructed of screen--ether sees
no resistance whatsoever in passing through our beings, indeed, all
matter exists as such to it ... I simply speculate that the EM
waves/radiations from an antenna have the power to interact with it
(and, possibly even Cecils' photons.)

Matter is mostly space, between each atom in your body is something like
a relative football field of distance--here ether exists.

Indeed, with the vast distances between the atoms/electrons in a current
carrying conductor--there is much which could happen to the likes of ether.

All

Can anyone point me to some simple designs for a home made 17 metre antenna. I am looking for some simple half wave dipole type designs. I have a short back yard and have struggled to put up a half wave G5RV (managed in the end with a pole on side of the house) so it cant be too long.

I have had a quick google search and did not come up with much.

Thanks for support

Andy

Suggest you consider installing the above antenna as an inverted Vee,
using that pole with the 2 legs sloping to suitable points .

Then you believe space is nothing?
Then you believe that the creation of the universe is jis the propagation of
matter through space?

What I said in no way disagrees with the article and besides that I know of
no published work of Einstiens that states what the article said. Perhaps
this was something he pondered at one time. I am sure he changed his

thinking on a lot of things over the years given the fact he and other physicist were breaking new ground at the time. The discovery that light always travels at the same speed relative to the observer opened up a real can of worms.

You appear to have real problem dealing with the fact that there is no difference between matter and energy, everythinhg exist in a dual state.

It is obvious Einstein was right, if you cannot state a simple model
which people can grasp, which obeys the rules of logic--all you are
running is a complex shell game.

Matter exists in the soup of ether ...

At some speed, the resistance of travel though the ether becomes of such
a significant drag or force, matter no longer can traverse without
resistance--this is the speed of light.

> You appear to have real problem dealing with the fact that there is no
> difference between matter and energy, everythinhg exist in a dual state.

I have no problem with matter and energy being composed only of an
altered state of the ether. But you are absolutely correct, I have as
much problem with matter and energy being the same, as the smoke, light,
ash and heat left from a tree burning, as it being the SAME as the tree
itself! DUH! But in a very pure sense--they are ... it can be argued
that the only real difference matters to life on earth.

The point Schroedinger was trying to make is that in the absence of information, there is no way we can absolutely know something. The very act of measuring or observing something causes the wave function to collapse and reveal an object's position, speed or some other state we are trying to establish. Opening the box and asking the cat seems eminently reasonable. The cat is never actually in a quasi alive/dead condition. In it's own 'universe' (box) it is either alive or dead. We cannot know which without opening the box at which point the two separated 'universes' collapse into one. Prior to opening the box it is necessary to consider both options alive or dead as a possibility but there is no third case where the cat is both alive and dead at the same time. The physical laws in our universe do not appear to allow for objects larger than a buckyball molecule of C60 to exist in quasi states.
Trying to establish whether individual photons or electromagnetic waves are emitted by an antenna suffers from the same difficulties. The very act of trying to establish what is being emitted will collapse the wave function of the photons or electromagnetic wave to reveal one or the other, but not both simultaneously.

In my previous experience in newsgroups, I'll agree that getting details from those who pose questions here is difficult, and I guess I'm as guilty as the rest. However, my original question was regarding details of common mode choke filter design and has apparently morphed into my RV setup.

The RV is a 31' class C, all fiberglass shell, welded aluminum frame, on a Ford E450 chassis and cab up front. Although I realize there are many aspects that could cause RFI in the cab area of the motorhome, I merely wanted to use a choke filter to see what improvement might take place.

The SG-237 tuner does not use a control line, so no filtering needed here. The DC will be pulled off the back of the motorhome close by, and that source, as I previously mentioned, will also be routed through a common mode filter.

The antenna feedpoint / loaded base area is about three feet down from the top of the metal ladder. The metal ladder vertical rails is one piece construction, and is bonded at bottom of both rails with 2" tinned copper braid to the main chassis rails with pieces running about 22" length. All in all, about as good a ground as can be obtained under the circumstance.

Clamp 'em on, recheck match/swr/your-chosen-methods-of-tuning (or, with the gods--for that matter) to antenna ...

It can't explode; well, I don't think it can!

Since the power flow is on the center conductor and the inside shield of the braid, any impedance of unwanted currents on the outside would, logically, be of some benefit ...

If it ain't enough, buy more or change to a different type of material. Knowing the expected values of components, and benefits to expect, would only put a lot of icing on that cake ...

This:

"The greatest change in the axiomatic basis of physics - in other words,
of our conception of the structure of reality - since Newton laid the
foundation of theoretical physics was brought about by Faraday's and
Maxwell's work on electromagnetic field phenomena.
Faraday must have grasped with unerring instinct the artificial nature
of all attempts to refer electromagnetic phenomena to
actions-at-a-distance between electric particles reacting on each other.
How was each single iron filing among a lot scattered on a piece of
paper to know of the single electric particles running round in a nearby
conductor? All these electric particles together seemed to create in the
surrounding space a condition which in turn produced a certain order in
the filings. These spatial states, today called fields, would, he was
convinced, furnish the clue to the mysterious electromagnetic
interactions. He conceived these fields as states of mechanical stress
in an elastically distended body (ether)."
(Albert Einstein, 1954)

Hi Ed,

Point in fact is that the "antenna" is actually a tuned radial, and it
is your "ground" that is the majority radiator.

This will be buried inside a completely unrelated thread, but there
are lots of "low power",
Part 15 100mW, devices in the MW band. There is a Military Graveyard
just about 15
miles south of me that has such a transmitter for "self guided
tours". I have seen/received
several "talking houses" including a solar powered one that I was very
tempted to visit
under the cover of dark and appropriate for my own use.

I have seen a few billboards with these also. Down toward Tennessee
the big firworks
outlets tended to use them about 8 years ago. I don't know if they are
still in use cause
I don't get down there these days.

Regarding my hunt for the UNID 1640 station rebroadcasting A NOAA
weather stream,

I had assumed by content it was at or near Cave Run Lake, near Morehead KY. But we visited there Friday and no signal. I talked to the Corp of Engineers and they suggested we check in Jackson. So off we went. As we approached Jackson it was clear it was not there. But I decided to check the Jackson Airport/NOAA office to see what they knew.

They were aware of the TIS stations in Winchester and Richmond that carried NOAA and were for use in the event of a nerve agent leak from the Blue Grass Army Depot in Richmond, but they knew of no station on 1640. They gave me a list of towns where there are low powered NOAA WX transmitters to check and it wasn't in any of them. On a lark we went to Richmond Yesterday and the TIS on 1610 is still only receivable right next the the emergency center. But there was a different station on 1640. This one is clearly connected with the Nerve Agent program and may be in Berea.

Sooner then later I hope to locate both 1640 transmitters.

I will post the main body of this under a new thread.

Terry

Oh yeah, Richard is quite correct there--don't choke off the counterpoise--but, I bet you already suspected that ... and, don't use the coax as a counterpoise! Well, unless you design for that ... but then, don't run the counterpoise in the inside of the vehicle ... well, your vehicle is fiberglass, kinda hard to hide from the antenna/counterpoise, but again, you already knew that ...

I got it--pun intended.

It should be becoming obvious that I have read Einstein--and believed.

Indeed, what other force can we produce upon the ether to achieve our communications? EM fields strike/push/pull/influence the ethers' strings ...

Those lines of force, seen in iron filings/powder, show "stress" of the ether--any engineer worth his salt will recognize these "stress lines" in a media ... in this case "gravitational ether"--an un-ponder-able media.

Used a single, whip antenna for both 10 and 11 meters?

I almost never use 11 meters but during hurricane chasing, It is a must.

I am looking for the best way to use one single whip antenna for both bands. If one band needs to suffer in performance, it would need to be 11 meters.

I can add a third antenna to my truck but with the distance between the 10 and 11 meter antennas being very close to each other and interaction may be a problem.

<PLEASE READ THE FOLLOWING>

I will never have both the 11 and the 10 meter rigs on at the same time.

What happens when 2 antennas that close together in frequency as well as distance apart from each other?

Is there a way to use such an antenna system?

Keep in mind that while driving in a convoy it is not a good idea to have to use antenna A-B switches etc...I would much rather just turn on the rig I need and off the one I do not need at the time.

Thanks for any ideas... BTW, the truck is a 2002 4 door dodge ram with the 11 meter whip mounted using a steakbed hole mount in the front drivers side steak hole. The 2 meter collinear antenna is in the front passenger steak hole.

Ed,

Some thoughts...

In the broad context of a sparse bonded metal frame work, and with your somewhat elevated feedpoint (though not fully described), it would be no surprise if most parts of the structure weren't at elevated RF voltages (as per Richard's summary of the antenna system).

The first steps to a solution might be to try to minimise the potential differences between the radio interfaces, the nearby structure, and the operator. I would be trying to bring the feed line down the ladder, along the chassis, and up the framework to the radio, and to bond it to the conducting structure at 1, 2, or 3 points along the way to try to ensure that the radio and operator are at similar potential to the adjacent conducting structure.

The effect of a choke is almost the opposite, it is to facilitate potential difference across the choke.

I am not saying that there might not be a need for chokes in the solution, but just chucking chokes at it until it works doesn't seem to work systematically through identifying the problem and then designing solutions to the problem.

Many modern radios are particularly sensitive to RF on the DC and microphone interfaces. If you split the radio to use a remote head, that exposes another couple of interfaces to RF.

The loss in 10m of RG58C/U at 14MHz with a load end VSWR of 1.5 is around 0.6dB. Why do you need RG8X, it must be much harder to deal with in a vehicle than RG58?

Owen

I might pick up a signal in the middle of the AM broadcast band but it
won't be yours, you're at 16.7 kHz.

Use two relays. Each relay opens the RF path to each antenna when
unpowered. Then energize each relay (appropriately) when a rig is
turned on. These can be cheap relays because they are either always
on or always off (according to the state of either rig).

NOW, if you emphasized us to read this section, and then slip us a
mickey that you "might" need to monitor the other band you are not
working, then shame on you.

Actually, that is step one, which is on the project table.
Currently, when operating HF fixed portable, I run the coax out the
coach, on the ground, and back up to the feed point. My plan is to
route it neatly from the radio location, down to the chassis, along the
chassis, out to the ladder and to the feedpoint. I suppose that, alone,
could help in my RF issues. They are not serious issues, but are
annoying at times.

Perhaps I'll reserve my ferrite split beads for a choke filter on my
fixed station antenna when I get to that.

Ed

Really?

A 360 degree rotation is somehow stuck with a divisor?

Do you divide the 360 degree "rotations" of your transmitters sine wave
with a large divisor also? Or, possibly your sine waves are greater
than 360 degrees?

Interesting ...

My error, I was thinking RPS (Rotations Per Second) but wrote rpm--'ya
got me, just not used to those high speed motors :-) ... and you MOST
CERTAINLY pick up my signal now ...

And, no, this motor doesn't come apart at this speed--the metal the
motor is made of came from the UFO crash in Roswell NM ;-)

http://www.audiosystemsgroup.com/RFI-Ham.pdf will answer a LOT of these sorts of questions. It has a cookbook for building chokes, etc.

The challenge is that the Radio Shack ferrites might be a mix more intended for suppression of VHF spurious signals than HF. I believe that the Radio Shack ones are either #43 or #61. Most of the snap together ones are #43 (optimized for 30 to 400 MHz, i.e. to reduce RFI for FM broadcast and TVI with rabbit ears).

For myself, I use 5 2.4" toroids of #31 material (Fair Rite #2631803802), and run a half dozen turns of the coax through it. It has about 30 dB of attenuation from 2-30 MHz. These run about $5 each in moderate (10-30 pcs) quantity, so the choke is around $25. Get a bunch of people together in a group buy so you can get 1000 of them, and they get down to the $2.50 each range.

J.C. Bose used dielectric lenses at 90 GHz back at the end of 19th
century (that is, in the late 1800s) when doing his experiments in Calcutta.

Optical techniques have been used in radio for a very, very long time.

Actually, you are partially correct. In the cookes radiometer, the
motion cannot be ALL attributed to the radiation pressure. A nichols
radiometer can accurately measure this radiation pressure ... the effect
(photons having mass) is real ...

468/18.1mhz=25.85 total feet for a half wave dipole. Divide by two for
each leg.
Feed with 50 ohm coax. Can't get much simpler than that. Can't get
much more
efficient either unless maybe you have to run 500 ft of coax. . :)

I've been a SWLer for years and am considering getting a ham license. However, I live in an urban area (Brooklyn) and wonder just how effectively I can transmit from here. Big outdoor antennas and ground radials are out of the question.

Obviously I'd be starting out on VHF and UHF frequencies, perhaps with only a modest handheld transceiver. Handhelds look pretty puny, but is this appearance deceptive? Would one allow me to talk to lots of people and learn from them?

Any insights you can share will be greatly appreciated.

Steve

There are two possible mechanisms here. One is a momentum exchange
effect which is orders of magnitude smaller than the other and can
only be observed at ultra high vacuum. The other (the one Denny
accurately described) is a radiative molecular heating effect which

creates a differential pressure and as such, can only be observed in at most a partial vacuum. The way to recognize the difference is that the two mechanisms produce their respective forces in opposite directions.

A current balun near dipole in the shape of ferrite cylinders or ,when
using RG58 type of coax, 7 - 9 windings of the coax on a larger toroid ,
will ensure no RF interference in the shack /house (eg no RF current
flowing along coax braid)
It is even better to use a balanced feeder instead of coax.
You then either need a matching unit for a balance feeder or use a balun
as described above near the transmitter ,connecting coax to feeder
through a dual plastic connecting block .

Personally I would always use a balanced feeder for any wire antenna.

Suggest you have a look at http://www.hamlan.org/tech/tech.htm.

20m loaded mini-dipole by IK2BCP (length 1.75 metres or 5 3/4 feet)

This is an antenna for QRP (low power) operation , but by using thicker
wire for the coils it will be suitable for higher RF power.

Results with this antenna are positively surprising.

>must be porous.

Not "my claim," my report. The claim they must be porous arrives through the math necessary to balance the kinetic forces. As that math balance (from Einstein and Reynolds) has never been achieved, then Denny's description has never been proven. Less than porous vanes only further removes such "explanations" from the realm of proof. In fact, as a description, Denny's is incomplete insofar as there is no description of the turbulence created in the near vacuum that serves as the "thrust" for the vanes which is missing in a complete vacuum. The "thrust" is optimal only for porous plates, as an explanation; and that explanation, as I've said, does not fully balance.

Now, if we simply move to another radiometer (Nichols, Tear, Hull, and Webb already recited) without that partial vacuum, the vanes still move, and expressely by Radiation Pressure. And the problem remains as to the balance of forces. In essence, these instruments indicate, not measure.

The coy context of the thread was measuring the mass of a Photon. Absolutely no SI Units have been named or any quantitative values offered (the rather standard omission from claims made here). However, feel free to introduce your own side thread's goal or even offer a guess (your own quatitative value for the mass). Such additional discussion would vastly elevate the inane repetition of claims above

the level of "Photons have the flavor of Crï¿½me brï¿½lï¿½e."

Use 50 Ohm coax (RG8X, or better) unless you are in love with your antenna tuner. I have tried it with and without a balun, and can't really tell any difference. However, right now there is a 1:1 current balun at the feed point. Trim the length for best SWR, 25.85 might be a bit long. I am using #14 stranded/insulated wire.

True. I usually just roll a choke from the coax. You don't need a
toroid for single band use. Or even 20-10 triband use for that
matter.. May have problems trying to do 80-10 well with a single
choke though.

> It is even better to use a balanced feeder instead of coax.

Only if one intended to use it for other bands.
For single band use it would probably have a higher system efficiency
using coax, being most that run ladder line use tuners, etc
which add some loss to the system.

> You then either need a matching unit for a balance feeder or use a balun
> as described above near the transmitter ,connecting coax to feeder
> through a dual plastic connecting block .

Dunno, I prefer to keep things simple. I would usually prefer a 50 ohm
radio, feeding a 50 ohm feedline, to a 50 ohm antenna.
Using a 50 ohm radio to a balun or tuner feeding a 450 ohm feedline to
a
50 ohm antenna seems kind of silly to me in comparison, if for a
single
band. But to each his own I guess..
BTW, I have compared the two, and the coax fed always slightly beat
the
ladder line/tuner fed system as far as efficiency on any HF band.
Of course, my coax runs are never over a 100 ft.. Often half that.
But when using a 989c tuner and ladder line, I could never get quite
the
system efficiency vs using coax, even using the most careful tuning
methods.
IE: using the minimum inductance needed to get a match.

>
> Personally I would always use a balanced feeder for any wire antenna.

I'm usually about the opposite. The only time I use ladder line is
if
I intend to use a single wire for multiple bands. In that case, I can
see it.
Or if maybe I had to run a line several hundred feet, but I've
never had to do that yet..
But for single band use, it's going to be very hard to beat the
efficiency of a coax fed system with any type of ladder line system,
unless maybe you use the "Cecil" no tuner method.
And then.. it's more work, and the feedlines have to be off the
ground,
coiled just so, etc..... :/ The coax can be running anywhere. Even
in standing water.. On the lower/mid HF bands where I'm usually at,
the losses using coax are so low as to be a non issue. Trying to
beat the loss by using ladder line is not going to make any noticable
difference as far as the line itself. But.. Adding a matching device
almost always will. :(I can actually see it on receive just A/B
comparing using the S meter readings as an indicator.
I have no problems with ladder line, but the usual claims of
better performance isn't really true in the majority of cases on HF.
Often, quite the opposite, because of the matching devices usually
used with ladder line systems. Their loss usually overshadows the
slightly lower feedline loss.

Now, on UHF feeding say a TV corner reflector-yagi thing I use for
ATV, I prefer the twin lead.
Unless it gets wet, it's gonna beat most runs of coax as far as the
system loss. In that case, the matching devices don't overshadow
the higher more noticable coax losses at those higher frequencies.

Yo Steve!

March right off and get that license. For VHF and UHF, there are repeaters to use, And I assume that Brooklyn and the surrounds has no shortage of them. I don't know hown many are private, but there has to be some public ones. As for HF, there are options even there. I talk to Hams from Brooklyn and thereabouts on even 75/80 meters.

There may even be clubs that have club stations located outside the city. Keeping in mind that if they have folks to Elmer you , you can get in a little HF work under a control Op.

Absolutely. Sometimes we get so caught up in big balls antennas
that we discount the little ones.

... Gaw, did I actually say that? ;^)

Point is, if you can't put up a 40 meter beam, don't let it keep
you from putting up a modest antenna.

All

Welll once again this proves the theory - two amateurs = three opions.
However, this is a very useful discussion and the 25ft (ish) simple
dipole seems to be the easiest thing to work with and the length is
very achieveable in the space. I therefore have to get to a decision
on what i use in the centre. I estimate from the centre of the antenna
to the shack would be approx 50-75ft max even if i run it neatly
around the walls. I am happy to use an ATU to achieve a perfect match.
So what do i go for?

Secondly, is there an optimal height. My half size G5RV is at the top
of the 30 ft pole so this would need to be below that? Also does it
matter if it is on a slight incline with the lowest part closest to
the house?

Many thanks for all the great advice

Andy

1245. Checking Coax Connextion

Hi Andy,

With both ends in your lap:
shells, end to end - very low Ohms;
pins, end to end - very low Ohms;
shell to pin, either end - infinite Ohms.

That reel of cable marked "balanced feeder" is a myth!

Twin feeder is not self-balancing. It never will be "balanced" unless your installation has MADE it balanced.

As it comes off the reel, twin feeder is capable of carrying unwanted common-mode currents just as easily as the intended differential mode. All practical antenna installations are unsymmetrical (either the antenna, its environment or both) so there will always be some unwanted common-mode current. Common-mode current will cause the feedline to radiate and will conduct unwanted RF back into the shack, where it often flows through into your house wiring... all of which is regarded as a Bad Thing.

Twin feeder will only become more "balanced" if you - the user - have taken some positive action to suppress the common-mode current. When you install a typical link-coupled ATU designed for "balanced" feedline, the low capacitance across the link coupling creates a high impedance to block the entry of common-mode current into the shack. A suitable balun

would also create a high impedance to block the common-mode current, so in this case you would need a choke balun (aka feedline choke or line isolator).

When you insert this high impedance in the path of the common-mode current, the current distribution over the whole antenna-feedline system readjusts itself to take account of this new factor. The new current distribution will be forced towards better symmetry on the antenna itself, with a smaller common-mode current on the feedline... so the feedline has now become more "balanced".

What should take the credit for this good result? It was the ATU or balun that you installed - so all the credit goes to you. The so-called "balanced" feeder deserves no credit at all, for it did nothing more than react to the change that you made.

Many people confuse the cause and effect here. If they believe that the feedline is in some sense "ready balanced", they will install a suitable ATU or balun "because that's what balanced feedline needs". Very often, it all works out OK because they have done exactly the right things, even though they misunderstand the reasons. But if it doesn't quite work, and something more is needed to suppress the common-mode currents, this wrong thinking comes completely unstuck.

Coaxial feedline has the major advantage that you can insert a choke balun right at the feedpoint, which substantially prevents common-mode current from being launched onto the outer surface of the cable[1]. The entire current distribution will then change, to take account of the fact that you have forced a minimum in the common-mode current at the feedpoint. Because the feedline is in the near field of the antenna, radiative coupling may cause common-mode current to reappear on the surface of the coax, starting with a new maximum a quarter-wavelength down the line from the feedpoint. But the size of this maximum is generally much smaller, and so too will be the residual current arriving at the shack - where, if needed, you can insert a second feedline choke. In really desperate situations, you can have as many common-mode chokes along the coax as you like.

With twin feeder, you don't have those options. Your only practical options are at the ATU, or where the twin feeder makes a transition into coax. That restriction makes it even less likely that twin feeder will ever be truly "balanced".

Bottom line: twin feeder has many advantages, especially for multiband operation... but automatic balance certainly isn't one of them.

[1] In coaxial cable, the inside and outside of the shield behave as two independent conductors for RF current, giving a total of three current pathways. The centre conductor and the inside of the shield have very tight coupling between their electric and magnetic fields, which ensures that their RF currents are exactly equal and opposite (the differential mode) and their net field on those two conductors remains

completely inside the cable. The third conductor is the outside of the shield, and behaves a a single fat wire carrying an RF current that is totally independent of what's happening inside. Although strictly speaking this is not a common-mode current, that's what it is generally called by analogy with twin feeder.

Hi Steve

Keep in mind that there are many many facets to amateur radio, not all needing large or even effective antennas. You mentioned handhelds. Some people use these through very simple directive antennas for satellite access. If you are into keyboarding, PSK31 around the world a simple antenna on 20m and 10-20W will do it. You can disguise it, tune a rain gutter or even make a loaded device only a few feet long.

Don't be afraid either, to go for a drive out into the country and setup on top of a hill.

Go into the hobby wherever it interests you. Just moderate your antenna size/shape/location accordingly.

Cheers Bob W5/VK2YQA

Despite the photon torpedoes fired at me, I have not seen a convincing physics experiment that deflates my previous arguement...

Where the F=MA arguement fails in a radiometer is that the photons impact both sides of the paddles leaving a zero net force for rotation...

The fact that a Crookes Radiometer requires an atmosphere is proof of its mode of operation. The fact that it has to be a partial vacuum further proves how it operates (more air density means too much air drag to allow rotation by the weak local differential pressure across the paddle)...

Those who reject local differential pressure changes due to local heating by claiming the pressure in the bulb is static ignore the factor of time in molecular exchange of thermal energy gains... Carrying their argument to the logical end means sun heating cannot cause the winds to ever blow across the ground because the net air pressure of Terra is static...

Damn, I knew I was missing something - no lap... <grin>

It is also worthwhile looking for signs of corrosion/water ingress etc
and wriggling the plug/connection as you use the Richard method. Stray
bits of wire can reach out and ruin your apparent resistance. (Which we
know of course is useless...)

(Apologies for using your post so flagrantly Richard...)

etc
========================
Ian , You are right ,I should have used the term 'twin feeder' instead
of 'balanced feeder'. Tnx for the correction.

In my situation the twin feeder from the dipole comes through a double
concrete block wall ,runs over the loft ,through the plaster board
ceiling (meeting very few metal parts) into the shack . No RF
interference anywhere in the house ,operating with approx 100 W PEP on
any of the HF bands between 3.5 - 29.7 MHz
I intend to make an RF current probe (2 half ring ferrite parts -diode
-connected to a DVM) to see whether there is any unbalance current .

This is more sensitive than taking the difference between measuring individual currents in the feeder lines.

My next activity will be to extend the feeder to a suitable length (Cecil style) such that I 'll be able also to operate on Top Band (1.8 -2.0 MHz) ,the dipole being 2 times 21.35 metres (2 x 70 feet)
With a twin feeder the actual length of the dipole is not critical , however in order to get a reasonably high current (low impedance) at the matching unit (of the E-Zee Match variety and the like) it is important that the total length of half the dipole plus the feeder is about an odd number of quarter wave lengths at the operating frequency .
The velocity factor of the 450 Ohms twin feeder I use is published to be 0.99 ,so for the above purpose it can be taken as 1.
This total length is more critical at the lower frequency HF bands because of the higher wavelength.

==========
The above is an electrical contact/insulation (DC) check

To check the quality of the complete coax cable including the plug(s)
a 'coax loss' check especially when operating at the higher frequencies
is important.

Some antenna analysers (like the MFJ 259/269) have this coax loss
measuring facility. These instruments enable the user to change
frequency which shows the overall quality of coax + fitted plugs.

The best type of PL259 plug is the one with a cable entry arrangement as
in N-type plugs . This provides an excellent and simple braid connection
,without having to apply heat other than soldering the centre conductor
to the top of the pin .
These plugs are somewhat more expensive than traditional PL259 plugs
(equivalent US$ 6 in the UK) but imho it is worth the expenditure.

All

More on the nature of the problem. I have basically fitted a 1/2 size
G5RV. Its fitted at 30 ft high between a pole at the end of the yard
and the chimney at approx 30 ft high. The ladder line falls pretty
much vertically except for the very end where i have had to divert it
away from a steel cast iron style balcony which surrounds a roof
terrace on the first floor. I figured it would not be good to brush
alongside the balcony as its metal.

Anyway, i am getting some very weird SWR readings even when i am using
my automatic ATU (LDG Z-100. These range from close to 1.1:1 on

40metres all the way up to 3.1: 1 in the middle of the 20 metre band. I am trying to work out where the problem may lie. So far i have come up wiith:

1) its just the way the antenna works and the ATU cant do any better?
2) the ATU is not working properly (but it seems to get a decent match elsewhere)?
3) there is a problem with the plugs (would this appear to make a difference only on some frequencies)?
4) somehow the stell balcony / balustrade is causing a problem even though i am keeping the ladder line approx 12 inches away from it. Also would this only cause a problem on 20M?
5) running the coax along the steel balustratde and into the house is causing a problem (is this possible)?

Confounding factor is that it seems to be working ok even with the high SWR and i have made some decent contacts on both 40 and 20 metres.

I thought i should start with the plugs but any other thoughts welcome - all very odd!!

Regards

Andy

Perhaps people should take look at other things that creat radiation!
For instance the explosion from a energy container such as a
transformer feeding a spark plug.
The frequency band is widespread leaving time varient current,
capacitance and inductance and neglecting resonant lengths. Can a
capacitance store a particle or can it blow away a particle formed on
its own material?Time varient obviously dependes on the size of the

capacitor therefore the time current is applied to the capacitor is
irrelevent.
I have left off references to icecream, snorkels e.t.c. even tho
apparently they are necessary.
Art

In a newly installed connector, the most common fault, by far, is a short from the center conductor to shield. Also, make sure that the opening in the center pin is completely filled with solder. For small coax, I usually stuff short pieces of heavier wire in there before soldering. You need a fairly large iron to solder the shield. I found a ~200 W soldering gun works OK.

Actually, given you can receive and transmit, the plugs was probably
the worst guess. All in all this is a case of losing your keys in the
road at night, and spending all your time searching under the street
light.

Are you, perhaps, under the impression that a G5RV (or any variation
thereof) "should perform better?"

Hi Denny -

The thing that seems to have certain people confused here is the fact
that, with regard to radiometers, there are two different effects at
work. Radiation pressure is in fact quite measurable, but is an

orders of magnitude smaller force than the thermal/molecular effect that toy store radiometers demonstrate.

Radiation pressure is such a small effect that it cannot be observed unless the vessel is first evacuated to an ultra high vacuum. Ordinarily, one would use a torsion or micro balance to measure this effect. But in a radiometer type arrangement, the vanes rotate in a direction away from the more reflective side because the change in momentum is twice as high for a reflected photon as it is for an absorbed photon.

But in the case of the thermal, partially evacuated (toy store) radiometer, the black side of the vanes absorbs more thermal energy and is therefore hotter than the white side which absorbs less and reflects more energy. Gas molecules which encounter the vanes in a partially evacuated radiometer are ejected more energetically from the hotter side than from the cooler side thus creating a net force in the direction away from the black (less reflective) side. This is as you described.

Hi Denny,

You need a better reading list. Researching the historical names
offered would be a start.

>Where the F=MA arguement fails in a radiometer is that the photons
>impact both sides of the paddles leaving a zero net force for
>rotation...

Well, the Newtonian math certainly fails (as does the Quantum math);
but not because photons hit (more properly absorbed by) both vanes
equally for a net zero force (an appeal to F=MA already dismissed). If
you observe the Crookes radiometer (and its brethren), it has distinct
differences in reflection/absorption characteristics which impart a
very considerable differential in the net force; which, again, do not
balance with the energy applied. This is not to dismiss the obvious
reaction, however; but no one here has offered any quantifiable forces
other than myself.

>The fact that a Crookes Radiometer requires an atmosphere is proof of
>its mode of operation. The fact that it has to be a partial vacuum
>further proves how it operates (more air density means too much air
>drag to allow rotation by the weak local differential pressure across
>the paddle)...

Unfortunately (and as mentioned several many times), the so-called
differential in pressure does not balance with the applied energy.
Even if it did, it would require a porous vane to make it work
(another negative hit). It would be useful if someone could offer
even one line of quantifiable data to support ANYTHING. So much of
this is testimonial that this should be called rec.radio.tent.meeting
given the general inclination to veer from facts towards faith.

>Those who reject local differential pressure changes due to local
>heating by claiming the pressure in the bulb is static ignore the
>factor of time in molecular exchange of thermal energy gains...
>Carrying their argument to the logical end means sun heating cannot
>cause the winds to ever blow across the ground because the net air
>pressure of Terra is static...

Hmmm, who could those heathens be? Perhaps the scurvy Nichols and
Tear whose radiometer works so well in a more complete Vacuum?

I might ask how much room do you have - indoors,attic, outdoors,
rooftop, etc.? Don't assume you need an acre for a decent antenna.

Let us know how much area you have to work with & we can make
suggestions.

You might find my article on optimising the G5RV of interest. You will need to scale for a half size G5RV, so scale the frequency axis of the graph times two, and when it tells you to check for an electrical half wave of open wire line at 14Mhz, you need to do it at 28Mhz etc. The article is at http://www.vk1od.net/G5RV/optimising.htm .

After some basic DC tests for proper and reliable connection, no short circuits etc, next is some more serious RF evaluation of the antenna system.

The commonest reason for a G5RV to perform worse than expected is that the open wire line is an incorrect length, usually due to not properly considering its velocity factor. (If you purchased a kit, as so many people seem to do nowadays, you would hope that the supplier got this correct... but?) Next is the length of the dipole which is often regarded as not affected by its environment. (This applies to a commercial kit as well as a DIY G5RV.) A tape measure is the start of setting up a G5RV, not the end.

==========
True ,but that has nothing to do with amateur RADIO.
This NG is mostly about amateur RADIO antennas.

In spite of all the conveniences of Internet linking ,let's focus on the
RADIO aspects of the hobby ,even at/from locations where the
installation of 'run-of-the-mill' antennas is a problem or outright
impossible

Owen

Yes it was a commercial antenna and i guess the last thing on my mind was measuring its length? mmmm.... now you got me thinking, Given this was far from the cheapest G5RV and from W&S rather than some unknown on ebay i would have hoped it was 51ft as described. Would i need to source a willing local fellow to come around with an antenna analyser or are there some simple tests. I will read the article and give this some more thought. Thanks for the ideas.

Source record: 36485

I thought I'd post the results of my recent little project to put up a Carolina Windom for 80/40/20.

Didn't work very well. :-(

At least, not yet. ;-)

I cut it for 3.6 MHz, and according to everything I read that should give decent performance on or about 7.2, 14.4, and 28.8 MHz.

Instead, I got 3.6 MHz (as expected), then I got about 6.6 and about 14.9.

I followed the instructions I found in one website article that said to cut the legs for 37.8 percent and 62.2 percent.

Other articles I've read say to cut for 1/3 and 2/3 of a half wavelength, i.e. feed the antenna 1/3 of the way from one end.

Since I'm a high precision sort of a dude ;-), I figured 37.8 and 62.2 were more precise than 1/3 and 2/3, so I tried them.

Like I said ... works well on 3.6 (and most of the rest of the 80 meter band) but not anywhere else.

It is built with a W2AU balun (4:1), 22 feet of RG-8X, an MFJ "line isolator" (1:1 current-type unun), then about 25 feet of RG-8X to the shack.

I guess I'll have to go back up there next nice day and try the 1/3 2/3 way.

So be it. The absence of porous plates in operating radiometers tends
to cast doubt on your report that the plates must be porous.

> The claim they must be porous arrives
> through the math necessary to balance the kinetic forces.

But a balance of forces would result in the absence of an observable
effect. An imbalance in forces is required in order to produce
movement.

>way.

The 14.9 MHz sounds about right, but the 6.6 MHz sounds
very weird. I would have believed 7.6. In general, the
40-meter resonance point will not be exactly twice what
it was on 80 meters, nor will the 20-meter resonance point
be exactly four times what it was on 80 meters. Generally,
it will be higher in frequency.

I have had good success in the past using the 1/3 and 2/3
leg lengths with a Spiro 4:1 balun and a bead balun right

at the feed point. However, if you really want this to work on 40 and 20 meters, you will want to make your antenna longer than you have.

I used legs of 45 and 90 feet. The SWR was about 1.0 at 3.5 MHz and 1.3 at 3.6 MHz. Actually, it didn't reach 2.0 until about 3.75 MHz. Lowest SWR on 40 meters was at 7.2 MHz at about 1.0 and was low across the band. The lowest SWR on 20 meters was at 14.35 MHz at about 1.0, but was 1.8 at the bottom of the band. By the way, it didn't look nearly so good on 10 meters, where the lowest SWR was 1.8 and quickly rose to over 2 at 200 kHz either side of 28.6 MHz.

Good luck with whatever you try.

73,
Bob

Hi Jim,

You should distinguish between reporting, claims, and what you see.
The point about being porous is to substantiate the expectation of
explaining the full energy budget (and specifically for the Crookes
radiometer). I don't know how many times I have to emphasize this,
but NO METHOD achieves that balance.

>> The claim they must be porous arrives
>> through the math necessary to balance the kinetic forces.
>
>But a balance of forces would result in the absence of an observable

The balance is in the energy applied and the energy expended. You put
an HP into a car, and it will accelerate 550 foot-pounds/sec. You put
x photons into ANY radiometer, and the change in inertia WILL NOT
balance.

[This is why I expressed my question in Newtonian terms for the
benefit of the twins who are so devoted to the master (that they are
wholly lost in a simple 2 variable computation). The difference
between that computation and performance is extreme. What is more
compelling, is that it is quite a departure from what Quantum
Mechanics would predict. NO METHOD achieves that balance.]

No. Power meters to even uncommonly high accuracy still conform to
Newtonian mechanics.

There are many ways to install the 83-1SP/PL-259 plugs. The instructions given on the Amphenol website (http://www.amphenolrf.com/products/assemblyInstructions/274.pdf) will show the basics. In addition to what Tam says (use LOTS of soldering iron/gun heat, and get in/out fast), I found a way to solder the plugs that have nickel plating on the connector body.

Nickel doesn't like to solder worth a darn, and it will take lots of heat to burn through it. By the time you do, the cable dielectric (and possibly the insulator on the cheaper plugs) will turn to mush. It's worse with foamed polyethylene vs solid polyethylene coaxial cable. Before assembling the plug onto the cable, remove the plating on the inside circumference of the plug. A small round file, X-acto knife, or 1/8" drill bit will do the trick. My soldering "weapon of choice" is a Weller #8200 100/140W unit.

If using RG-58, you have the option of using an Amphenol "field crimp plug", PN 83-58-FCP which requires no soldering, no special installation (crimping) tools, and works VERY well. Larsen supplies them in their permanent mounting kits. I intalled lots of them at a previous gig. One day, I did a test of how well they hang onto the cable. I installed one on a scrap piece of cable, hooked the connector into a vise, and pulled on the cable until something gave. The cable broke. They're $2.92 each (in QTY = 10 to 24)

from Digi-Key.

> Why has ether become synonymous with "kook?"

From Wikipedia:
"Einstein in later years proposed calling empty space equipped
with gravitational and electromagnetic fields the "ether",
whereby, however, this word is not to denote a substance with
its traditional attributes. Thus, in the "ether" there are to
be no determinable points, and it is meaningless to speak of
motion relative to the "ether." Such a use of the word "ether"
is of course admissible, and when once it has been sanctioned
by usage in this way, probably quite convenient."

Ives was the first to positively measure the effect of speed on clock
rates. He wrote in 1940 in a paper in Science:

"I have considered the popular claim that the ether has been "abolished"
[...]. Reverting to experimental findings I have reviewed the experiment
of Sagnac, having in mind the claim that the ether can not be detected
experimentally. I have asserted that, in the light of the experimentally
found variation of clock rate with motion, this experiment does detect
the ether."

The screwdriver coil can certainly be used in the middle
of the 40 foot vertical wire to tune the system to resonance.
Bury some radials and you are in business.

Thanks, Bob, I will try your measurements.

I don't really care much about 10 meters and if I ever do get interested in it I'll probably just toss up a ground plane.

The SWR figures you mentioned sound fine to me, the autotuner in the TS-940S can handle the SWRs I'm getting now so it'll be able to handle those while never breaking a sweat.

I don't understand the 6.6 MHz either, very strange.

Hi-potting would be better as it *may* find whiskers which the
multimeter will not, but the multimeter will find the majority of
problems.

An even better way is to file *across* the holes, cutting the brass body
down to two thin feather edges which are easier to solder.

> My soldering "weapon of choice" is a Weller #8200 100/140W unit.
>
For anyone who doesn't already have a large iron, I'd recommend buying
an inexpensive hot air gun instead.

If you use the hot air gun to pre-heat the connector body, your existing
25W iron can handle the soldering part.

Another use for the hot air gun is with heat-shrink tubing, so it's $20
well spent. The only risk is that someone may ask you to strip paint
with it.

1278. Hy-Gain AV640 (Patriot) problem, or Bugs in the Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-06 07:46:50 UTC
From: "Roger (K8RI)" <validaddress@my.com>
Message-ID: <n09vd31a287h7tl3rvpouh5pmu6lhp6ovn@4ax.com>
Source record: 36496

I put up a Hy-Gain AV640 a few years back for a backup and as the HF antenna for my shop. The antenna was on top of a 32 foot aluminum tower at the West end of the shop. The match on all the bands was near perfect, or at least it was slightly better than I'd expected with 1.1:1 at resonance. Bandwidth on each band was more than adequate and much wider than any trap, multi band vertical id used in the he past.

I had mainly been listening to W1AW code practice on 40 but did make a few contacts on 40 and 6-meters.

I recently replaced the old Henry 2K4 with a Tokyo Hy-Power HL-1.5KFX solid state amp which happens to cover 6-meters as well. With the little Yaesu FT-897D it also gives auto band switching and will remember which of two antennas connected to the amp you were using for each band.

At-any-rate a couple weeks back 6-meters opened up and a spent a few hours making contacts from the East, West, and Gulf coasts. (no DX <sigh>) When I went to operate on 40 the amp was kicking out due to high SWR and started doing the same on six. Both 40 and 15 were resonant about 1 MHz below the bottom end of the bands. Minimum SWR at resonance had gone from 1.1:1 to between 1.6 and 2:1.

We (several other hams and myself) let the Tower/antenna down. It had one broken insulator which would not have caused the problem, but I built a new one out of Lexan which is a lot more sturdy than the old *stuff*. THEN I got to the matching network. That thing was packed solid with Wasp nests and crispy crittered Wasps along with a pile of dead Wasps and Wasp *goo* on the coax chassis connector in the bottom of the box. That goo made it through the chassis connector and badly corroded about 3' of 9913 which is being replaced with LMR-600. NOTE the original drain holes are just a tad too large and just right for Wasp entry for their new home. So if you use one of these antennas, plugging the drain holes and drilling a series of smaller ones might be in order. OTOH Hy-Gain does state you should take the antenna down and clean out the matching network every year or so. (Wasps can build a *big* nest in a few days)

Apparently there is some truth to the RF exposure hazard, or there was for the wasps in close proximity to high power on 6-meters. None of them complained when I cleaned the nests out. BTW I had to completely remove the tuning unit from the box to be able to get the nests and *glue* they make off the torroids.

Having the antenna down, I took the opportunity to give it an overhaul. I cleaned all the connections which looked pretty bad (lots of white powder), used a tiny bit of nolox (similar to Pentrox) on each coil and jumper connection after cleaning, which was then sealed with liquid electrical tape. The jumper from the tuning unit to the counterpoise had to be replaced. After 5 years the fiberglass is showing some deterioration due to UV exposure. Be careful about coating these coils while trying to protect the fiberglass. The coils are right under the top hats and clear Krylon or liquid electrical tape may add a bit of capacitance in parallel to the coils and with them being right under the capacitive hats a little capacity can go a long way resulting in the resonant frequency going down substantially for that specific band.

I put the antenna back up on a 14foot pole anchored to the NW guy anchor for my big tower. On checking, the SWR for 40, 20, and 6-meters is just where it's supposed to be as is the resonant frequency and the SWR at resonance is showing 1.0:1. However two bands, 15 and 10 are showing 1.6:1 and 1.9:1 at resonance. (resonance is back where it belongs) All solder joints in the matching network have been resoldered and checked. Wires and cores were also checked for insulation and burn marks. Tech support told me not to worry about running 750 watts output PEP even though the ratings show 300 watts for 6-meters as long as there were no signs of overheating or arcing. The network should handle that with ease.

So the problem, or question is, why the change in minimum SWR on 15 and 10 meters? What may I have missed? The analyzer is no help for this.

I gotta get that antenna system on the big tower repaired and the rotator reinstalled for the DX season. Then maybe I can set up an interconnect so I can use those antennas from the shop as well while keeping the AV640 as a backup. I rebuilt the PST-61 (seals failed and water took out the main bearings) and it's ready to go back in. Unfortunately nature gave me a bit of a set back last April and I had to learn to walk again. However I'm about ready to tackle the tower work real soon. I've been working at 30 to 40 feet, but that doesn't take near the energy of climbing to 100', working for a couple hours, and still have the energy/strength to climb back down.

BTW I had been working on top of the guy anchor post Thursday afternoon for about a half an hour when I noticed a couple of bees flying around. They weren't bothering me, but when I looked down into that 5" pipe I saw a very large Wasp nest with Wasps crawling all over it. At that point I hosed it down with Wasp and Hornet killer. I decided I had pushed my luck far enough.

Human natures are fine tuned for gene pool survival.

The way we evolve in the gene pool is that when we're not at war, we're in a race.

Peace and freedom means competition. Some people are uncompetitive. So they don't want to compete. Those people demand slavery.More...

Those who demand slavery are not necessarily poorer or richer, superior or inferior. Those are people that somehow do not like competition.

The farm owning farmers in southern US, for example, do not want to compete with the higher salary the industrial north has, so they demand slavery. This happens despite the fact that the landlords are already way richer than their slaves.

Uncompetitive businesses also do not want customers to be free to choose the best products. They demand enslavements of consumers by restricting consumers choice to choose better products.

As time goes by and consensual productive means to aquire wealth become available, those who oppose competition tends to be the one inferior.

When we're not at war, we're in a race. So in a sense, some part of life is a zero-sum game. The happiness of some superior competitors correlate with gene pool survival of such people. This correlate with the extinction of inferior people and this make inferior people unhappy....page...

For example, women prefer rich smart males and normal males prefer as many females as possible. Actually poor males prefer more money rather than more women, but that's later.

If rich smart males get more females, then rich smart alpha males will survive better in the gene pool. That means, the other males do not get any. Hence, the lesser males will not be happy. They will then come up with monogamy to ration females in equal share for everyone.

Those who are uncompetitive are not going to say honestly that they are disgruntled competitors. They're going to come up with some religious unscientific fairy tales to come up with pretext that freedom, such as free sex is wrong.

In short, whenever someone is happy, whenever something gives pleasure, happiness, and money, you can count that someone, somewhere, somehow, will come up with some fairy tales of who knows what that

somehow it's wrong, bad, and should be prohibited.

The preference to snuff of happiness earned by others are called envy. In a sense, those who want to be happy are meant to kill each other with those who are envious.

Unless those who run the fastest also hit the hardest, success is simply a bridge to a gas chamber. Deviation from free fair competition turns life into some form of gun fight.

Not everyone can be appeased in a gun fight. Envy is simply unappeasable. The way to keep pursuing our happiness and still be alive is either to kill, or threaten to kill, those who are envious of us that it's not to their best interests to kill or prosecute us....page...

That's why I strongly support death penalty. Without it, all succesful people will be slaughtered by bigots that don't mind going to jail for it.

It's also the same reason why many ugly women oppose porn. That's because those women are envy bigots.

Think of it this way. Pretty women can just show some skin and make millions of dollars. Ugly women has to sexually serve poor males and get knocked up for much less money.

If this keeps going, pretty women can pick the best males with the best genes and provide their sons with better education, opportunity, and more initial start up capital.

The pretty genes will survive better in the gene pool and the ugly will be outcompeted, like in Europe or Japan. All thanks to porn.

Obviously, pretty porn stars are way better of then ugly wife. Becoming a porn star or prostitute is then one of the best job ever in this world.

However, out of envy, ugly women will want to prevent that. What's their justification? By saying that all the good jobs are so bad that it can't possibly consensual, and hence has to be prohibited.

They said that porn should be prohibited to protect women. Which women? Not the consenting one of course. How in the earth people get protected from consensual offers anyway. It's there to protect disgruntled envy competitors.

Its just not called ether anymore, Its space-time. Again when the universe was created it created space too, not just propagating matter into space. Beyound the universe there is nothing , within the bounds of the universe there is space time or as Einstien called it then ether. The difference in the concept is that ether was considered something inside of space now it is considered as space. Space can be bent and shaken, no need for ether to explain anything.

A blackhole is able to suck in massless photons because space time has been warped not because of attraction with a massless object.

Jimmie

Yes, that annoying fact, clocks slow when you place 'em on jet aircraft, refuel the aircraft in flight, and make a few trips around the circumference of the earth.

In my present state of thought, this directly relates to the speed of light; further, I suspect, the ether is responsible in establishing the, seeming, barrier of the speed of light. As you approach the speed of light, things are not linear, you must apply magnitudes more energy without corresponding gains in speed. And, although I tend to believe the math which "proves" this, it ends up just another thing I fail to completely be able to wrap my mind around. But, it seems at the speed of light, traversing the ether with matter offers such a resistance to the speed of matter, any further increases of speed are impossible--no matter the amount of expenditure in energy ...

At this point, I am just happy to be in the company of others who will, at least, accept the possibility of the ether, and the possibility it can/does have real effects/affects on our material world.

Regards,
JS

Hi Jim,

Sounds like you should talk to your Chaplain about these issues.

>I've often wondered how one might go about recognizing a
>photo-electron out of a group of other, less prominent electrons? :-)

It is like complaining the Nobel winners are indistinguishable from
the crowd in the ceremonial hall.

Prominent is key, certainly. How many electrons can you motivate to
leap over the barrier of the work function of a metal? In Physics, a
simple population count would reveal the prominence. Tubes usually
have to boil them off incandescent filaments, or rip them out of their
matrix with 10's of kilovolts of nearby potential.

Hi All,

Let's examine those last two motivators. Photons hardly raise the
temperature of a metal vane to, what, 1000 degrees? And as for
kilovolts of excitation, how much potential is there in a photon?

Well, too often this group starves for information in response when I
toss these questions out - too technical for this forum of light
nappers I suppose. Too often, these threads turn into strings of
slaps at the snooze button (and "ether" has been the biggest snooze of
them all - self-fulfilling if one were to enlarge on the term's
rhetorical baggage).

Place a vane coated with sodium into an evacuated quartz tube.
Illuminate the sodium coated plate such that it absorbs one microwatt
per square meter. This is sufficient power to evoke the
photo-electric response (hopefully this is not too arcane a term). The
bulk of absorption will occur within a layer depth of 10 atoms.
Sodium, one atom thick, measures out to 10^19 atoms per square meter,
so we are absorbing the power throughout 10^20 atoms. Hence each atom
is illuminated with 10^-26 Watts OR 10^-7 eV/sec. (eV: electron Volt,
perhaps another prominence hard to embrace.)

The conundrum (sorry for hard words - but even those who use English
as a second language manage to cope) here is that to build a potential

to at least 1eV (and usually 3 to 5 times that for many metals) would take nearly a year for a single electron to leap the Work Function barrier. In reality, it occurs in less than a nanosecond.

It would be interesting to see Arthur's Newtonian math achieving a 10,000,000,000,000,000:1 leap of faith. False idolatry in place of work is like putting a lottery ticket into the collection plate.

Strip away my stylistic excess and the facts fill maybe three sentences. Still, I am four sentences ahead of the rest. ;-)

John
The universe is made of many things. Most all are held within the
confines of a gravitational force.
There are many of these gravitational orbits but one thing is for sure
is all these individual orbits
or gravitational forces are in equilibrium with each other even to the
magnetude of including all
the stars and the galaxies. All mass known is in the final borders of
the total equilibrium outside
of which there is no mass or external forces which has been named the
AETHER. Equilibrium of moving parts
means changes of the shape of the extreme borders within equilibrium
is held .When the equilibrium boundaries change
the shape of the eather also must change and eventually must be
included in an equilibrium of sorts

Equilibrium is a poor choice of words when you encompasses the ether, in my humble opinion.

You are attempting to give known states/laws/rules/properties to a material (ether) which Einstein himself tells you NOT to--Einstein implies a proper model for the ether was not available during his lifetime, I do not see where that has changed, to date.

Indeed, in pure form, equilibrium implies a static state--anything more implies an over unity condition (perpetual motion), the forces which drive the motion and birth of stars-planets and the expanding of the universe is/are NOT in a static state, in six billion years a static state has not come into being, in another six billion years it is not expected for it to come into stasis--only if this will remain true "forever" remains a question.

As long as matter exists, the above will, seemingly, remain true. A state of "un-equilibrium" exists in the sheer fact that all matter has been ripped from the very fabric of the ether--this I suspect is a most unnatural state of affairs (no one can be sure, for sure--and we only have one example to view! Other explanations exist ...) ... we will know when we have "seen" the ether and know of the laws/rules which govern it and its' un-ponder-able properties.

Hi Tom,

Your link is over valued (there is no second response), but it
maintains the standard of excellence here in the tradition of 10k-100k
more words than quantifiables - and someone else doing the work.

Care to walk us through your proffered math?

Well, I doubt it. Others may be interested in the curious form of
argument offered to a 15 year old however.

"For a particle with no mass, the relation reduces to E=pc."

The long and short of it is that there is no discussion of mass for a
photon (it is simply defined not to exist) and instead there is a
shuffle of math that youngster must imagine this bozo is pulling the
wool over his eyes through substituting p for Planck's constant h, and
c for Planck's energy formula variable v. This wool pulling is
another favorite past time here too.

Of course, there may be other meanings behind
"E=pc."
but in the model of thorough work, the description of terms is sadly
poor.

The typical legacy of offering links. It has all the appeal of a
Physicist's joke:
"How many milliseconds does it take to do a 5 minute car wash?"

Yes, and p=mv, so when v=c as is true for photons, and we substitute mc for p in the equation above and then solve for m (the mass of a photon was the original question), we're back at the equation offered previously.

But we usually relate more directly to the frequency (or wavelength) of the photon rather than its energy or momentum, so in such a case E=h*nu would provide a more direct route to its mass equivalent.

I live in the top story of an old Victorian house. So, I'm relatively high up, and there's a big, sturdy fire escape at the rear of the house. There's also a modest backyard that I have access to, but with the exception of a small, receive-only loop antenna, I've had bad luck putting antennas back there. Eventually I might be able to arrange an antenna on the roof of the house, so long as it's not too big and noticeable. However, I think any antenna I use though will require a balanced design because my grounding options are severly limited. Maybe a small transmitting loop would be a good choice?

I believe we view aether differently as well as the term equilibrium.
The later describes what is balanced within a border and where
momement of the
interned is reacted by countermovement in the shape of the border.
This is why I keep comming back to Gauss

and his description of static particles. True the border varies in shape exposing
cracks or deformation of its borders where particles can escape before equilibrium
is reformed as internal forces or orbits correct their positions so the retaining border
becomes of uniform strength again. If the innards were not mobile and adaptive to change
then once the border was fractured it could not adapt and heal itself. This bordcer in itself
is balanced as part of other gravitational borders all of which are expanding and regenerating into
different border and thus expanding into the aether which has nothing to provide resistance.
The main point is that all that is contained must have movement so when the balanc eof equilibrium is momentarily broken
it is in a position to adapt its internal movements to attain equilibrium again. How else can one adapt to escaping particles and collisions
if there were not constant movementof that which holds together because of equilibrium.
True Richard will take exception to this as he views himself as Einsteins successor and is determined to block in his own eyes everything
except what spills from his own mouth with the suggestion that he knows all but has not yet decided to disclose it. The same with respect to his credentials that allows him to judge thoughts of others.

Art:

You seek to answer the unanswerable, you seek to explain the unexplainable ... this is far from "being wrong." It simply proves that our knowledge is incomplete, at present. This is something we all hope to cure in the future. Now, we simply debate the different explanations which exist. Magnetic fields certainly play a prominent part in manipulations of EM waves/particles, and the opposite ... what is going on precisely is up for grabs, again, in my humble opinion.

The fact is, although I think we can see the stress lines in the ether with the simple iron filings, paper and magnet, we know nothing about it--indeed, the "proof of its' existence" I am citing might have yet another explanation. Indeed, at this point, ether almost requires a "leap of faith" such as necessary with a belief in God. By sheer definition we cannot even devise a bottle to hold a sample of ether.

However, cowards will run from the unknown, brave men will sit and discuss how to attempt to prove it, one way or another.

A system with equilibrium will, at some point, cease movement, unless there is an input of energy from an external source, this energy might appear cloaked in many forms. Can we at least agree upon this single point, first?

Even better is to do both. Removing the plating inside the hole will
promote the flow of solder across the junction of connector body to shield,
which is what we want.

Message-ID: <1189134024.315816.199930@22g2000hsm.googlegroups.com>
Source record: 36520

Greetings:

Requesting reception reports on our new NDB beacon LYQ on 529 KHZ
just below the AM broadcast band.

Can you hear it??? What is your QTH???? please post reports
here!!

We tried a shunt fed tower some weeks back and gave up on it due to
poor beacon range.

We are now using a 130 feet high flat top antenna with a horizontal
run of 250 feet between two 140 feet high towers.

The flat top antenna has a Vertical wire 130 feet high connected dead
center to a cable that is suspended and insulated from the two
support towers.

This antenna is an 'traditional' NDB beacon antenna

Driving in my car with the car radio tuned to 530 khz I can hear the
beacon loud and clear for 40 miles!!

When we used the shunt fed tower tuned to a VSWR of 1.1 to 1 the
range at best was
15 miles

Using the same ground radials

we are located about 50 miles south of Nashville,TN just off of
I-24 Manchester,TN

Thanks for the reports!!!!

Hi,
I am replacing the wire in a trap on my 3 element Tri-Band beam
antenna...
The wire is 25 turns of approximately 10 gauge on a 1.210 inch form
diameter, with a coil length of 3 inches(these numbers are
approximate).
I am unable to get the exact gauge(10 AWG) of wire and was wondering
if there would be any adverse effects in using a slightly smaller
gauge wire in place of it,say 12 gauge or so...?

Any help with this would be greatly Appreciated
Thank You

Sorry, I cannot have explained that clearly enough.

If you do what I suggested, there is no point in removing the plating
from the inside wall of the hole first, because you're going to file all
of that metal away.

Keep filing until the inside wall is completely gone, and the hole is
surrounded by a sharp edge that tapers to zero. At that point, stop
filing - it's ready for soldering.

Hi Jim,

Tom opines about my reading, but it is about the writing from the good
doctor that we find (in regard to your snippet above):
"we find that the momentum relation p=mv is
only an approximation. It is only correct when speed (v) is much
smaller than the speed of light (c).
which distinctly contradicts your tie-in:
>so when v=c as is true for photons, and we substitute
>mc for p in the equation above and then solve for m (the mass of a
>photon was the original question), we're back at the equation offered
>previously.

The circularity of Dr. Ken Mellendorf's foggy writing might suggest
it, if it weren't otherwise nipped in the bud by the bald statement.
"For a particle with no mass, the relation reduces to E=pc.
This works for a photon."

Hence the proximity of this to p=mv is textual, not factual.

What is the term p? Could it be (p)hoton? I've speculated about
Planck's constant (which you comment upon, below), but I find it very
sloppy writing for Dr. Mellendorf to wander into his own naming
conventions. Migrating through
E = mcï¿½
something all can agree is a fair basis to begin with, we then have
expressly for a (p)hoton:

E = pc
Substituting for the previous E
pc = mcï¿½
divide both sides by c
p = mc
which to me is new territory. What is mass times the speed of light
for a particle that has no mass?

Perhaps Tom's special reading skills can rescue this p term from the
oblivion of E = 0 for a (p)hoton.

>But we usually relate more directly to the frequency (or wavelength)
>of the photon rather than its energy or momentum, so in such a case
>E=h*nu would provide a more direct route to its mass equivalent.

Yes, and it seems your daughter trumped me on Planck once before. ;-)

It is exceedingly obvious that the link offered amounts to
considerable wool gathering. Or maybe its the late hour....

I can "see" a CW signal on 529KHz with baudline on the Linux PC, the TS680S HF TXCVR and the 7MHz dipole!. It is currently about 10dB above the (FFT) noise here. (6AM) I can barely or not at all hear it.

I am not however satisfied that it isn't a birdie or other RF source. (It disappears with the antenna unplugged) There appears to be no ident on the signal. What is the period and method of identification?

Where do you live that you can't get 10 gauge wire?

If you use 12 gauge wire, you will likely end up with the frequency of the trap being off. If you have a dip meter, you can measure the resonant frequency and adjust the number of turns and/or wire spacing to get it where it needs to be.

Let me see if I have this straight. You are filing on the round part of the connector barrel where it has the 2, 3, or 4 holes for soldering to the shield. You use a narrow flat file, and file just short of the point where the holes would become oblong?

A nonsense question since "no mass" for a
photon is associated with it being *at rest*,
i.e. *not moving at the speed of light*.

> Perhaps Tom's special reading skills can rescue this p term from the
> oblivion of E = 0 for a (p)hoton.

For a photon possessing zero rest mass,
traveling at the speed of light yields
a finite measurable mass.

Pretty much... I hope this picture helps make more sense of it:
http://www.ifwtech.co.uk/g3sek/misc/pl259.jpg

I actually use a 5/32 round file or rasp. Stop filing when the hole is
just beginning to become larger, and has thin, sharp edges all round.
The thin edges and bare brass make soldering much easier.

Or split the difference between the two bands when you trim the antenna for lowest SWR. Then turn the power back in both rigs (wink - dang, something flew into my eye) to around 5 watts (if you have a 100 watt rig) and don't worry about the SWR. Not enough heat being developed at 5 watts and a high SWR to damage anything if the rig is rated for 100 watts into an SWR of 1.5:1 (or thereabouts) or lower. You don't need no esteenkin' switches or relays.

Of course, "I" wouldn't do anything like this. Too much too lose.

I think you should make those comments directly to him so that he an
opportunity to respond. Shall I forward them for you? :-)

> What is mass times the speed of light
> for a particle that has no mass?

Seems like something is wrong in that sentence, doesn't it.

> Perhaps Tom's special reading skills can rescue this p term from the
> oblivion of E = 0 for a (p)hoton.

It's also possible that since E=0 is wrong, the assumption that p=0
might also be wrong. If not, then you'll need to explain radiation
pressure in an all new way.

> Yes, and it seems your daughter trumped me on Planck once before. ;-)

She's better at math than I ever was.

MK has given the proper way to do it - but then there is "MY" way. <G>

I have one of those cheap ($200) metal sheds that I bought from Home Depot a while back. The kind that takes you and someone else nearly an entire weekend to assemble because of all of the screws.

Well, mine leaks water, but it is still better than having nothing at all...I think.

Anyway, if you happen to have one of these all metal sheds, plop a magmount, or a through the metal mount, with a 17 meter Hamstick on it and call it a done deal. Will it work as well as a dipole? In some directions yes and in some directions no. You won't equal the dipole's broadside radiation, but you can stomp the grape juice out of its end point radiation. <G>

If the band is open, you don't need a fancy antenna or a lot of power. If the band isn't open, no one is going to hear you even if you are running full legal limit power output. I run my little Yaesu FT-817ND QRP rig on this set up and it talks around the world - when the bands are open.

The good thing about this set up, if you're a digital and CW man, in addition to phone, is that you can replace the 17 meter Hamstick with any other band Hamstick and still have some fun. PSK-31, Amtor and Pactor with 5 thundering watts and a Hamstick will yield amazing results. The key is patience and knowing which Hamstick to put in place.

Gonna have a terrible storm and you're worried about your Hamstick? Well, you can always remove it - OR, you can buy ten quick disconnects off'n a fellow on eBay for a ridiculously low price and fold over and lash down your precious Hamstick.

Anyone can talk all over the world with the best antenna, highest power output, etc. QRP can bring back the excitement of operating once again, assuming you're not a 75 meter rag chewer. For the latter, they truly need the best antenna and amp in order to be heard. Just the nature of the band. However, scoot down to 80 meters and once again, QRP and minimal antennas gain a great measure of equal footing.

I'm no expert (although play one on TV), but I thought that the process at work was reflection of the photon, which shows a measurable doppler shift. The doppler shift lowers it's wavelength. The wavelength increases, and energy decreases. That energy has to go somewhere, and it goes into the sail and takes the spacecraft or whatever is attached along for the ride. So it really isn't a mass issue - although it is possible that the solar wind which does have mass and may contribute some small push on the sail. But that is another issue.Photon push is a radiation pressure energy transfer mechanism.

I use a Weller SP-175 iron. With 175 watts and a 5/8" tip, that
combination of heat and metal mass means I only spend 3 or 4 seconds
at each braid hole, and no filing is needed even on cheap nickle
plugs.

To each his own :-)

For the lurkers who may care to sift a tiny bit of wheat from the
chaff, see common physics symbol usage at
http://www.alcyone.com/max/reference/physics/symbols.html,
http://selland.boisestate.edu/jbrennan/physics/notes/Introduction/physics_symbols.htm,
http://www.hazelwood.k12.mo.us/~grichert/sciweb/formulas.htm and
others. If you're reading physics writings, it helps to have an
understanding of the language of the physicist.

See concise explanations about photon momentum and relativistic
momentum, energy and mass in general at

http://hyperphysics.phy-astr.gsu.edu/hbase/relativ/relmom.html,
http://physics.mtsu.edu/~phys2020/Lectures/L6-L11/L8/Relativistic_Momentum/relativistic_momentum.html
and others.

> Thank You

I echo Scott's question: why is 10AWG so difficult to get?

But I also ran some numbers for you in a program I use often and trust. Even if the absolute values are off a bit, the relative values should be very close. Here's what I got:

3" long, 1.21" ID, 25 turns, 0.120" winding pitch = 3"/25

Parameter	10AWG	12AWG
inductance	7.148uH	7.053uH
wire length	103.1"	101.4"
Qu@14MHz	592	660
Equiv. par. C	1.68pF	1.67pF
Self-resonance	45.9MHz	46.4MHz

The inductance error could be corrected by winding it slightly larger diameter; but it should be easy enough to just re-tune. The higher Qu of the smaller wire is probably accurate; the larger wire is wound too close-spaced to get the optimum Qu.

Cheers,
Tom

Steve,

You are right on the balanced antenna, there is no way you can have
an RF earth from your height. I live in a first floor apartment and
have a fan dipole (80m to 6m) in the attic fed via a balun and then
co-ax to the rig. There are details on my website.

Charlie.

Good afternoon, Bob.

Since it's 92 degrees and about 95 percent humidity out, I decided now was a good time to go outside and do some antenna work. :-)

I reduced one leg and increased the other to get the 45 and 90 feet you suggest, but I must have cut it a bit long, because I'm getting SWR dips of 1.12 at 3350, 1.1 at 6.701, and 1.4 at 14.4.

Band edges are:

3.50 -- 1.5
4.00 -- 3.8
7.00 -- 1.75
7.30 -- 2.8
14.00 -- 1.9
14.35 -- 1.44

This is the Carolina Windom configuration (more or less...) 4:1 W2AU type balun, 22 feet of RG-8X, and a 1:1 current unun, then 25 feet of feedline which is currently sort of looped back on itself (really only need about 8 feet).

I was really hoping to get the antenna up higher than it is, because right now the bottom 3 or 4 feet of the 22-foot segment, and the unun, are lying on the roof, but it's as high as I'm going to be able to get it for the foreseeable future.

Performance seems on a par with, or slightly inferior to, my 180-foot inverted V fed with ladder line and an LDG autotuner. But, I haven't really had a chance to test it yet. And, the inverted V connects to my old IC-735 which has far and away the very BEST non-DSP noise blanker I've ever used, much better than the one on the TS-940S which currently hosts the CW.

When I get a chance I'll dig out a coax switch and connect both antennas to the same radio for some apples to apples comparison tests.

You might try a horizontal loop around the perimeter of the top floor
of your building. feed it anywhere along the circumferencewith open
wire & a tuner & youll have a decent all band antenna (also relatively
quiet).

The 11 meter rig is A cobra 29 limited classic...It is stock. I have no
need or wish to modify it as the only time I use it is to talk to truckers,
going in the opposite direction. (I dry out buildings for a living and it's
nice to know what roads are open and the last place to get fuel when going
into an area hit by a hurricane)

The 10 meter rig is an old rat-shack HTX-10 ...25 watts.

The cobra does have some kind of a manual tuner in it. I have no idea how
well it could match an antenna cut for say 28.8 MHZ. I would think not very

well.

I have no problem with the 11 meter side having a high swr as long as it does not damage the rig. Also, the 11 meter rig has a little red light that comes on if the antenna is mismatched and I am not sure if the rig cuts the output power in that situation.

I guess I could always have 2 whips. One cut for 11 and one cut for 10 and change them when needed but I was trying to avoid that..

I tried the same scenario in the inductance calculator at
http://hamwaves.com/antennas/inductance.html .

It suggests that the inductance is quite a bit lower (~6uH), but
interestingly, that larger diameter wire gives a lower inductance rather
than higher.

That outcome seems counter-intuitive considering an ideal solenoid, but I
suspect it is caused by a very different estimate of the self capacitance
(0.6pF).

Wouldn't it be simpler, cheaper, and easier to just use crimp connectors? There is the cost of the crimping tool and die set, but it's a one time investment, The cable is much easier to prepare whether you strip it by hand or use a stripper, and the connections are much more mechanically sound than the standard PL-259.

BTW I do solder the center pin even after crimping.

Good, silver plated PL-259s run on the order of $2.50 each (give or take depending on how many you purchase. Silver plated N-type connectors run around $5.00 USD, again give or take depending on how many you purchase and they use the same die set as the PL-259s.

Considering cost and durability I've gone to all crimp connectors in place of the solder type.

I water proof connectors and splices with MMM, flooded heat shrink tubing. http://www.rogerhalstead.com/ham_files/connectors.htm shows the application of the tubing although that was before I went to the crimp connectors.

I'm getting a foreign-language broadcast station on that frequency, on three radios (FT-1000, TS-940S, IC-735) and three antennas (two inverted Vs and a Carolina Windom).

Whatever it is is way too strong to hear an NDB through.

Our vacation house has about 75 of plastic rain gutters on 3 sides of the flat roof at about 20 feet up (2 story). I was thinking about laying a 40m dipole in there with no connection to anything on the house. The only question I have is, is that there is a 2" strip of metal flashing about 8 inches above the gutter, for the length of it. How bad do you think this would screw up a dipole that's essentially parallel to it?
This station would be for emergency use primarily to talk with a station about 85 miles away with mountains in between so it doesn't need screaming dx performance... ground waves and cloud warming is all that's necessary...

It will act somewhat like guy wires which can cause
distortion in the radiation pattern and losses.
With any luck, it will have a high impedance and
not have much effect. Try it and see what happens.
Worst case, you may need to cut a slit every 1/4 WL
to keep the currents low.

Thanks, I may just whip up a dipole and do that! Was also looking at
a RadioWavz Bazooka on 40m as well... dunno how that would compare
since it radiates differently... only one way to find out!

1339. Trouble with MFJ-269 and local AM broadcast station

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-08 22:16:12 UTC
From: "Bob D." <bobmgtd@insightbb.com>
Message-ID: <iu2dnSpX2o61gn7bnZ2dnUVZ_r2nnZ2d@insightbb.com>
Source record: 36457

I bought an MFJ-269 antenna analyzer with some 160 meter antenna design in mind. It works fine on my VHF and UHF antennas, but the local 1350 AM station (which is just a half mile away) interferes when an HF antenna is connected. The SWR reads >31 and the two analog meters dance to the station's audio. I tried a home made 1350 KHz notch filter I've used with a few receivers. The notch filter gets rid of the offending signal, but makes the 160 and 80 meter readings bad (verified with a dummy load).

Any solutions out there? Is it possible to build a 1350 KHz filter that won't throw off the impedance reading at 1800 KHz?

Luckily my Kenwood TS-570 is able to contend with the AM station.

Bob,

MFJ makes something to do that, called the MFJ-731. I live near the WSM-AM tower, and definitely can "see" them when I do HF work. I am primarily a VHF-UHF operator, so I can't give you more than a cursory report. The MFJ-731 seems to take care of the problem without introducing significant inaccuracies.

Wow, a miracle antenna. Their claims include:

Advantages:
* Broad bandwidth
* Almost unaffected by environment
* Positive gain with reference to a common dipole operating under the
same relative conditions up to 3.6 db
* Greatly attenuates harmonics(almost eliminates interference!!!
* Substantial decrease in static charge build-up
* Non-directional. (as a inverted V)
* Great for DX!!!

Can you believe that?

But wait, you wanted more: http://www.radiowavz.com/html/bazookas.htm .

My study of a typical Double Bazooka antenna system at
http://www.vk1od.net/DoubleBazooka/index.htm indicates that although it
might have slightly greater VSWR bandwidth (FWIW), it has more loss than
a conventional dipole.

Though it is likely to be poorer, I doubt you would notice it... but why
go to the trouble and expense for something that is likely to be poorer?

I believe Walter Maxwell also wrote an article about that a few years
back.
There is no free lunch with the double bazookas. I don't use them
myself.
Not so much because of the slight extra loss, more that coax weighs
too much to use as antenna wire unless you have really strong
supports.
Regular wire is also a good bit cheaper. :/

Walt did indeed write on the Double Bazooka. Ch 18 of Reflections II is dedicated to the topic.

If I understand his discussion properly, Walt treats the coax stubs as pure reactances, ie lossless. My analysis treats them as lossy transmission lines, and the outcome will be different for that reason.

Further, my analysis treats the system as a system, and so captures the effects of feed line loss, so it is more complete.

My article also models the cross-connected Double Bazooka which is supposed by some to address the deficiencies of the Double Bazooka. The VSWR bandwidth is greater, but at the expense of even higher stub loss.

Hi Bob,

Call the station, ask for the Engineer. Then ask when they go off the
air for testing. You may be up late into the wee hours, but for only
10 minutes or so.

If you are going to filter the AM out, you have to look through that
filter to see the antenna. Your experience has already borne out the
futility of that. However, I've seen just such advice in the past
with recommendations of charting things through a Smith Chart. I
can't say I have much confidence in that outcome - still, it may beat
out the alternative of waiting a month for the scheduled down time.
Even then, I would still get up that night and get the benchmark.

sounds like a regular dipole will do the same for less :)
always interesting to see different designs and opinions tho!!

If you're open to getting another analyzer here's one to consider. I
have used my AIM 4160 at a friends location which is about ï¿½-mile from
a local broadcast station and it worked fine for 160-metrer antenna
adjustments -although the local BC station runs only 1 KW.

Here's a link showing what you can expect using the analyzer for your
situation.

I have the BC filter for the MFJ259... Never could make heads or tails
of the so called 'instructions'...
I find that using EZNEC for getting initial element sizes and resonant
frequencies, then using a grid dip meter followed by a transmitter and
an RF current meter for final tuning has always worked for me...
I do use the MFJ259 quite a lot, but for my 80 and 160 arrays the
voltages from rectified BC getting into the analyzer often screws it
up... My best time is middle of the day when there is less propagation
of BC signals - usually that is when I am at the office, however
<sigh>...

I am in need of a rubber ducky antenna for a PCI wireless card. It's the one with the reverse SMA connector.

If anyone on the list has an extra rubber ducky PCI wireless antenna with a R-SMA connector, please contact me off list and we can make arrangements for me to get it.

Thanks for the bandwidth.

MFJ sells a tunable band pass filter, which you would tune to 160 m. By the
way, a high pass filter won't work either. I built a 2 MHz high pass filter
to use on 75 m, but it affected all readings below about 5 MHz. My AM
stations aren't real close; so, the 269 works OK on 75 m during the middle
of the day.

Hi Henry

Since I already sent you a brand new antenna at no cost to you, I wonder
what your needs are for this collection of 2.4 GHz antennas.

Jerry,

I have a PCI card without an antenna that I picked up at the Goodwill.
I was going to put it in my computer in my ham shack yesterday and
found I had lost the antenna you so graciously sent me. I couldn't
remember who sent it and for that I apologize. I put the card in
anyways and connected an antenna from a different computer and
everything works, so now I'm needing an antenna again.

I have turned this house up upside down and can't find it.

Despite lots of static crashes, and BC Band bleed through (though I could not find the BC station that matched the QRM I was receiveing) I was able to hear LYQ at approx 08:00 UTC, 40mi northwest of Cedar Rapids, Iowa.

Received with an Icom-706IIG and an 80M Carolina Windom.

Thats about 562 miles.

I've read some of the other replies, and some of them seem to suggest
unnecessary complexity in obtaining a solution.

First, what does your 1350kHz notch filter consist of? Let's assume it's
a simple series-resonant L/C to ground across the TS-570 RF input/output
(or somewhere across a 50 ohm coax transmission line between a
transmatch and the TS-570 RF input/output). If the L/C ratio is low
(smallish L, biggish C), the notch will be relatively broad, and
relatively deep. If the L/C ratio is high (biggish L, smallish C), the
suck will be relatively narrow, and not so deep (due to the additional
losses in the L). Either way, the notch may be broad enough to pull down
signals at 1800kHz.

At 1800kHz, the notch circuit will appear as an inductor across the
TS-570 input/output. If the reactance is not considerably more then 50
ohms (ie effectively an RF choke), you will lose signal level on
receive. On transmit, it will cause a poor SWR (looking out of the
TS-570). What you need to do is to sharpen up the notch on the LF side.
All you have to do is to parallel-tune the effective inductance of the
notch (at 1800kHz) by adding another capacitor across the trap (not just
across the L). You tune this capacitor so that, at 1800kHz, the trap
circuit appears a parallel-tuned circuit (infinite impedance) across the
TS-570 RF output/input. There should now be very little loss of signal
level, and a good SWR. Obviously, you may need to re-tune the capacitor
slightly as you QSY across the 160m band. On 80m, a much lower value of
capacitor will be needed.

Does this explanation seem to be applicable to your situation, or do you
have something different, which requires a different solution?

1360. Re: Trouble with MFJ-269 and local AM broadcast station

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-09 23:02:12 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <13e8urq3fhsh330@corp.supernews.com>
Source record: 36478

One kind of filter you can use with antenna analyzers is a "half wave" filter. This is an LC ladder network which has the delay and impedance transformation properties of a half wavelength transmission line *at the design frequency*, so the load impedance appears at the filter input. It can be made with either a lowpass or highpass frequency response, with the attenuation beginning not far from the design frequency. While it's not by any means the sharpest cutoff filter you can build, it has respectable attenuation beyond the cutoff frequency. It will alter the impedance if you get very far from the design frequency, but for some bands you can probably get by with a single filter, provided that the impedance you're measuring isn't too far from the filter Z0 (see the next paragraph) -- you should check with known loads at the frequency extremes you want to measure. The cutoff might not be adequate for the 160 meter/1350 kHz problem at hand. You can cascade more than one for better attenuation, but then the frequency range limits become more restrictive and the filter construction more critical.

A "half wave" filter is made by cascading two "quarter wave" filters. A "quarter wave filter" is simply a pi network whose elements all have a reactance of Z0, where Z0 is the impedance of the transmission line which the network imitates. 50 ohms is of course the most commonly chosen value, but you'll get more extended frequency operation if you choose a Z0 which is fairly close to the impedance you're measuring. For a lowpass, use inductors for the series elements and capacitors for the shunt elements. For a highpass, use the opposite. When you cascade two "quarter wave" lowpass filters, you have a C-L-C-L-C (shunt-series-shunt-series-shunt) configuration, where the middle C is twice the value of the end Cs. A highpass looks like L-C-L-C-L, where the middle L is half the value of the end Ls.

The inductor Q has to be decent, but not spectacularly good. I use type 6 powdered iron cores for the HF range. Type 2 might be a little better for MF. Because of the low loaded Q, these filters are quite forgiving about construction and small value variations. Give one a try -- they're easy to build.

I live in a high-level RF environment, especially from TV transmitters. I use my antenna analyzer for a lot of different things -- just about everything except analyzing antennas, in fact, which ironically is the one thing it's most poorly suited for. When I really need to know an antenna's impedance (at least up to 60 MHz), out comes the GR bridge, with an old Icom R1 receiver as a tuned detector.

>could the Ground plane due to its proximity create the
>white noise. in conjunction with the beam?

Hi Mike,

Not normally. "Normally" means antennas do not, in and of themselves, originate or source any signals. Some might, but even more remote from "normal" is sourcing white noise. (Generally, an otherwise passive antenna might become a re-radiator due to corroded joints/connections. Even then, it requires an actual, active source to make your antenna do what it might be doing.)

>I recall this problem a few
>years back with a Vertical on my house and the ground plane that is
>the same one 40' away except the white noise was only S-1

Progressively higher noise over the years suggests weathering which further suggests corrosion (see above).

>...It looks
>very obvious there is some interaction.

"Obvious" to you, perhaps. You might want to explain why.

>I just can not figure out what
>it is. Suggestions from those that may know. I will be lowering the
>Ground Plane that is 40' away from the house to see if that helps. All

>in advance Mike

Keep your antenna up there. It is too slim a chance of being the culprit (at least until you explain what was "obvious"). You might also tell us what you mean by "white noise." Is this across the entire HF spectrum, across just the 10M band, or simply noise out of the speaker on your usual frequency?

Thanks for the replies everyone

Scott,
Could you please explain how I can use a grid dip meter to measure
the
resonant frequency and adjust the number of turns and/or wire spacing
to
get it where it needs to be?
I just picked up a grid dip meter but have never used one.

I'm not completely understanding the math required in figuring
inductance out...
I am able to figure out that with my coil form and number of turns the
coil I have is around 6.5uH but I cant figure out how to work wire
gauge into the equation? I have been trying to find someplace that
explains it but am unable to.
Could somebody here maybe explain how the math works when you throw
wire gauge into the equation?

Tam,
I am replacing the wire in the trap because when I was cleaning the
corrosion off,the last inch or so of the wire broke off and since the
wire is aluminum I figure I would be better off replacing it then
trying to repair.

Thanks for the help everyone
Its most Appreciated
Regards

Classic wire-wound, air-cooled resistors.

You could do better with the various 1 meter diameter loops sold commercially. Some might suggest mobile screwdriver designs clamped to your balcony railing, but that isn't really the same sort of metal bulk equivalent to a, say, Chevy Suburban which would be the principal radiator. On a comparable price basis, the loops will be a better investment for 40M and up (I don't recall any that suggest they cover 80M and certainly 160M is beyond the realm).

A simple test for small (for their wavelength) antennas is to measure their bandwidth. We will take the Slinkies as an example (and certainly cheap enough to test this statement, and to see how they perform both). A small antenna that would be efficient will also exhibit a high Q. The loops mentioned, as I recall, generally exhibit 5 to 10KHz bandwidth. For the most part, they exhibit some of the better efficiencies (although not as high as a standard dipole).

The slinkies stand to have a wider bandwidth due to their loss (small wire AND steel wire). Initially, this may seem to be quite attractive, and if you ignore the loss, they may serve your purpose quite well (SWR and Loss are not always limitations to enjoying the hobby). As I said, cheap enough to simply plunge on and worry about efficiency later.

Tune-up can be as simple as stretching/compressing the coils until you achieve a match (at least that has been my experience). If the frequency is too low, add more slinkies. If you want to beef up the efficiency with a slinky, make it(them) part(s) of a center loaded element(s). Unfortunately that means more room than you have in your apartment situation.

The second antenna will not be the cause of your problem.

The fact that you can kill the noise with the ANC 4 means that it is not "white noise". It must be some form of coherent interference that the beam is picking up. Is the problem worse in one particular direction?

What antenna are you using as a secondary one for the ANC4? That antenna must be seeing the noise as well for the ANC4 to be able to cancel it out.

Also you don't say what frequency the problem is on.

I see that height above ground affects the gain and the angle of the
main lobe. (actually all lobes) The info I've seen shows best gain and lobe
formation somewhere between 1/4 and 1-1/2 wavelengths above ground.
So I have a 2.4Ghz yagi, does that mean I should put it 1/4 to 1-1/2
wavelengths
above ground? That means it would be 1-1/2" to 6" above ground.
Mike

Good afternoon, Mike.

1/4 wavelength above ground seems might low to me in any case... it's only
16 feet on 20 meters.

I think that any such numbers you find, though, should be considered
minimums. Higher is generally better.

For example, 1-1/2 wavelengths at 20 meters is 100 feet. Now, that's
mighty effective height for a 20-meter beam, but I don't buy that it's
more nearly optimum than, say, 150 feet. I might believe that perhaps
once you get above 1-1/2 wavelengths at non-line-of-sight frequencies,
anything more may be an exercise in diminished returns.

As for your example at 2.4 GHz, don't forget that 2.4 GHz, like all UHF
and most VHF bands, is a line-of-sight band. You don't generally get skip
like you get on HF and low VHF. So, comparing, say, 14 MHz to 2.4 GHz in
terms of antenna performance vs height above ground isn't a valid
comparison.

Maybe a better question would be: How many readers
know of anyone who has tried a Slinky antenna and
hasn't discarded it? IMO, one can always do better
than a Slinky dipole.

Hi Mike,

All very true. However, the best gain aimed through your neighbor's
hubcaps isn't very useful.

Another point, at the frequency you are talking about, that "gain"
coming from the reflection from ground can be absolutely useless, or
worse, render a poor bit rate throughput (the appropriate topic thus
turns on the term "Fresnel Zone"). The principle mode of
communication is line-of-sight. In other words, you want both
antennas to be literally within "sight" of one another. For greater
range, you don't necessarily want more gain, you want more height.

More height gets you above the hubcaps and kneecaps of the world, and
out into blue sky where the sun, moon, and the stars are seen by
everyone. Very little power is required to transmit to the furthest
point on the terrestrial horizon. With an antenna mounted 100 feet
high, that is only 14 miles away and 100mW will give a clear signal
(at least at VHF). Adding more gain won't make that signal any
clearer, but you might want gain if the transmission power is in the
microwatts. Then you add elements.

Returning to the allusion to Fresnel Zones, this is where reflections
from the ground (which raises the "gain" you noticed) or nearby
buildings add out of phase and distort the bit shape of digital
transmissions. If your location is susceptible to such problems (and
forces a lot of retries in packets); then you want more "gain" in the
sense of actually achieving more selectivity. The antenna's added
elements react to these blurring reflections less, and focus on the
line-of-sight signal more.

The link Owen put in his posting is to a pretty complete on-line inductance calculator. The one I use is similar, in that it uses a helical waveguide approach, though it probably does not include all the "tweaks" mentioned on the link page. Wire gauge plays a part in several ways. If the basic formula uses coil inside diameter, then note that larger wire puts the current further out, on average. If the wire spacing is much greater than the wire diameter, the current in the wire will be nearly radially symmetric: if you look at a cross-section of the wire, the current density will depend on the distance out from the center of the wire because of skin effect, but will not vary much at any angle for a given radius. But if the turns are closely spaced, proximity effect will re-distribute the current on the wire so it's no longer radially symmetric. That will affect the inductance.

A grid dip (or these days, just dip) meter is used to find resonances. You want the trap, when it's in the environment it's used in on the beam, to be parallel resonant so it presents a high impedance to signals at some frequency. So in a 20M-15M beam, an element with a trap resonant at 21MHz will look like a high impedance to 15M signals, and decouple the ends of the elements from the inner sections, which in turn are designed to operate on 15M. On 14MHz, the traps look inductive (the inductive reactance is lower and the capacitive reactance higher than at 21MHz, so the _parallel_ combination looks like a net inductance), and that means they look like loading coils. As a result, the elements on 20M including the outer sections and the traps-that-look-like-loading-coils are shorter than if they didn't include the traps. You can extend that reasoning to a tri-band beam.

You'd probably do well to practice with your dip meter with some resonant circuits "on the bench." You want to couple the meter to the coil of the resonant circuit to get a dip. To start, you can couple it closely, but the dip will be hard to read well, since the resonant circuit you're measuring and the one in the dip meter will interact strongly, "pulling" the dip frequency. So when you get a strong dip near a reasonable frequency, pull the dip meter further away, till you get just a gentle dip. Then the frequency readout (assuming the frequency scale on the meter is accurate) should be accurate. As with most instruments, it's good to get some experience with a dip meter so you have an idea when it's giving good readings and when it's in error.

Cheers,
Tom

The dials on Dip Meters are usually not very precise and may be inaccurate while loaded by the
circuit under test. You can improve your frequency determination by listening to the dip meter
signal on an accurate receiver or with a frequency counter coupled to the coil.

Thanks for the reply,
So, I need to get it off the ground, or in my case the boat.
I'm mounting it onto the aluminum roof of a boat.
How many wavelengths above ground (roof) would be considered Free Space?

Regarding transmission power: it's not microwatts but it is 18 milliwatts.

Fresnel Zone; I didn't really understand the why, but jist of it is, an
object
can be outside the line of site, but be in what is called the Fresnel Zone
and this object will attenuate the signal.

Thanks, Mike

Hi Mike,

I'm not sure that is very important in the scope of practicality. More about what can go wrong below.

>Regarding transmission power: it's not microwatts but it is 18 milliwatts.

Sufficient for a lot of applications. Given you are on a boat, you have your limitations. I don't suppose the horizon is more than 10 miles away if it is a sail boat with a tall mast. To another, similarly equipped boat, you can roughly double your range. Standing on the deck of a small boat, you probably can only see out to 3 or 4 miles.

>Fresnel Zone; I didn't really understand the why, but jist of it is, an
>object
>can be outside the line of site, but be in what is called the Fresnel Zone
>and this object will attenuate the signal.

No.

Fresnel also goes by the name "picket fencing." This means that reflections from nearby objects, and the direct signal cancel each other. There are dead zones for reception. Shift things a half wave (not very far for the band we are talking about) and they add constructively. There are also intermediate zones which for digital transmission can be problematic. For mobile operations like VHF in a car, the signal from a fixed source will alternately fade and build as though you are listening through a picket fence rushing past the window. A choppy water can really create a witch's brew of wave mixing (no pun intended).

Here, the solution is a gain antenna that is focused (aimed) at the source giving it a stovepipe view, so to speak. This cuts down on all reflections contributions and you do this not for the gain, but for the directivity (which is euphemistically called gain). However, a highly directive antenna, up high on a boat, in the same chop, will bob and weave and runs the risk of that stovepipe view looking somewhere other than at the source. Mixed bag.

Perhaps, but I put one together about 30 years ago, hung it on the apartment wall (inside), and made lots of contacts with it. I just stretched it or compressed it until the SWR was reasonable. I recall that the tuning was indeed pretty broad, so I suppose that there was more loss than you might see with a more conductive wire -- or it could have been due to the effects of the adjacent wood and plaster. Actually, I may not have had an SWR meter, but instead tuned the output tank of my Heath Apache for peak and dip. I miss that boat-anchor.

Still, it was small, and it worked well enough to get me on the air. I think I used two slinkys soldered together for each leg of the dipole, and stretched them out to about 15 feet. I operated on 40 meters. There are better small antennas, but sometimes "good enough is perfect".

This information is not really relevant to your situation. The best beam formation is in free space, but at HF this is not practical, the antenna is nearly always too close to the ground for the ground effects to be neglected.
However at 2.4GHz you can get many wavelengths above the ground, and practically the answer is higher the better. Ideally you should achieve line of sight between stations, and also be sufficiently high so that intervening ground does not encroach into what are known as the Fresnel Zones (the low vale ones at least).

"Increase of the existing HF noise floor by widespread use of PLT (BPL is called Power Line Telecommunications (PLT) in Europe)...will bring up problems for Military Radio Users as well as for HF Communication Intelligence (COMINT) in all NATO countries. The signal-to-noise ratio thus may be reduced for tactical and strategic HF radio as well as for fixed sensitive COMINT sites."

So not only is BPL a bad idea for amateur radio and shortwave broadcast, it helps the terrorists! But hey, at least someone on our side makes a profit (well, maybe).

If like me you live in an apartment and cannot erect external
antennas but do have access to a loft (or have a very small garden)
then a slinky may well enable you to put out a signal on one of the
LF bands. In my case I wanted to able to work the UK and into Europe
on the 80m band.

You see what I did at http://www.radiowymsey.org/FanDipole/slinky.htm

Of course it's a compromise and an 80m dipole would be much better
but it will work and you will get a signal out.

Charlie.

The Slinky was a pretty popular antenna when I was in the air force back in
the 70s. On the weekends you could run a coax out the dorm window and put up
a tem antenna in the trees. Weekends got to lok like field days for a while.

1388. Update Re: "Extension" antenna ?in?sanity check, please?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-12 10:15:57 UTC
From: Don Bruder <dakidd@sonic.net>
Message-ID: <46e7bc5d$0$14120$742ec2ed@news.sonic.net>
Source record: 36407

As some may recall, about a month ago, I asked about the feasibility of running 802.11 down a hunk of cable TV coax. The responses showed me that was a "major unlikely". To put it mildly.

I'm happy to say that despite that avenue not working out, functionality has been achieved.

(Warning: Here comes "Don goes into advocate mode" verbiage. The rest of this post may sound like an ad. It's just a happy customer.)

With a D-Link "ANT24-0700" antenna. Was going to build a cantenna, but I was in Staples for paper, and when I walked through the wireless section, I spotted this unit. Figured "What the heck - I'll hold on to the receipt", and dragged it home. The package copy claims it to be a "7dBi Omnidirectional High-Gain indoor antenna".

Yeah... OK... Package copy is nice, but I'm not interested in that alone. I want results.

Unpack it. Nice and simple - cut the ears off the plastic and take it out. It's in two pieces - a heavy (with nice little rubber "button" feet) magnetic base unit that's more of a three-pointed star than a triangle (and has provisions for, and comes with a "kit" for wall-mounting) The second piece is a "rubber ducky on steroids" antenna whip - Real close to a foot long, with an RP-SMA connector to thread onto the base, and a hinge, just like the machine's original-equipment ducky. A (package claim - I didn't bother to measure) 1.5 meter RG-178 cable connects it to an RP-SMA connector that screws directly onto my card. (No need for the SMA-TNC adapter that came in the package with it - use the adapter, and I've found that you can screw it onto a Linksys router, though) Set up, it looks pretty much like an overgrown, standalone version of the original equipment "rubber ducky" antenna.

And it sucks in the signal. In spades. Swapping from the card's original duck to this thing took me from a display showing "no networks detected" to a "signal strength is off the chart" connection to the target Linksys wireless router before I had a chance to look back to the screen after screwing it on.

The advice is to put it on the router, but... <shrug> According to "the rules" I can't do anything with the router anyway, and it's working just fine attached to the remote machine, so I'm happy enough with it. Betcha if I hung one of these things on the router itself, the signal strength would be as good as (maybe better than) having a wired connection.

Color me "tickled pink".

<end "Don does endorsement" mode>

Source record: 36409

I have a RF switching unit that multiplexes 4 input RF ports to 12 output ports. The unit carries RF of a frequency range from DC to 1 GHz. It carries GPS signals and other RF from an antenna.

Can you advise me of the design of a test jig to accurately test this unit? The test jig will contain a Network Analyser.

Where I have a split path or differential measurement, do I always have to use phase matched and batch matched cables?

Does my test jig switch calibration loads between ports? The cal load being an open, a short and a load.

Do I get the paths the same by using phase matched & batch matched cables, and then do a vector gen to save a 'footprint' of the test jig when it is in a known good
state?

How do I minimise errors introduced by imperfections in the test jig? I am looking for the test jig to measure the absolute SWR and insertion loss of the RF switching unit, using S parameters.

I know of someone running both 10 and 11M from one radio. He took a
block of steel and mached holes in it to mount two antennas on one
side and a ball mount on the other. The holes for the antennas were
about 6 inches apart anf the ball mount was half way in between on the
opposite side. The 10M antenna was cut for the high end of 10M and the
11M antenna wass cut for the low end of 11M. Antennas were full length
1/4 wl whips. OF COURSE you would never run both 11 and 10 from the
same radio.

Modern vector network analyzers will provide for calibration at the ends of cables, even if the cables go through relays or splitters or whatever. The the cables (plus other components) introduce error only to the extent that they are not perfectly constant and that they introduce loss which decreases the signal-to-noise of the measurement. Vector network analyzers commonly can do a full two-port measurement in one setup; that is, they have the ability to measure transmission and return loss in both directions, and that may save on the number of setups required.

You didn't directly mention a desire to measure isolation. You didn't mention if you want the tests to be fully automated, or run through operator intervention: three possible scenarios are that an operator connects a pair of cables from the VAN to certain ports on the DUT and adds some terminations, runs a test, changes the setup, runs another test, ...; an operator connects a complete set of cables from a test jig which includes loads and path-switching relays and then initiates the test sequence; or some machinery connects the DUT to the test jig and runs the tests. In the first case, the "test jig" is very simple--in the other two, it's considerably more complicated. You didn't mention the accuracy you need to achieve. I'm a little puzzled by the "DC to 1GHz" and the "GPS signals," in that GPS RF signals are in the

range above 1GHz.

We do testing of a somewhat similar nature here, using RF relays to switch the test configuration for different tests. It's important to calibrate such a system, and you need to establish how often the calibration should happen. Because of the number of ports involved, your calibration may be a bit tedious, so it could be an advantage to insure that you use especially stable cables and other components so the calibration doesn't have to be done too often. It's also important to do a careful error analysis so you understand the source of the errors and their expected magnitudes. At first look, I'm not seeing that you need matched cables in your system, but you do need to calibrate the net effect of the cables and whatever switching you use, and account for the variability as cables are flexed and as relays close with slightly different contact resistances each time. It's possible that your accounting will tell you that those variabilities are so far below your allowed tolerances as to be unimportant, but you should think about them in any event.

You'll probably find it worthwhile to carefully document your thinking about the design of the test system, so that if anyone asks in the future you can show them just what went into the design.

Cheers,
Tom

1393. G5RV & Tuner Question

Newsgroup: rec.radio.amateur.antenna

A friend bought a G5RV Lite and has a Kenwood TS-480SAT, hoping the ATU in the Kenwood would be able to tune all bands.
But only two bands would tune - 6m and 10m.

He then borrowed a G5RV Jr. Same results.

So question is does G5RV's in general require an external tuner with a wider matching range than the typical internal ATU's in late model rigs??

The Shadow usually knows. (;-)

The shadow would probably suggest you to try changing the feedline length a
bit to 'see what happens'.
I love the g5rv - especially on 20 m

Yes. Most tuners in radios are not much more than glorified
"line flatteners". They were never intended to match antenna
systems per say. They are intended to use with antennas that
are tuned, or in the "ballpark" so to speak.
The main purpose of the tuner is to provide a wider usable
bandwidth for the radios finals when using existing antennas.
IE: say you had a dipole that covered 3.7 to 3.9 mhz.
The tuner will let you run say 3.55 and keep the radio happy.
And the losses with such a setup are still fairly low.
The tuners were never intended to run "all band" antennas
where the Z can be from very low to very high.
For that, you really need a outboard tuner made for that job.
And if you go that far, might as well ditch all the G5RV
"junk" and just run ladder line all the way from the tuner
and the antenna.
You could tune the feedline to get a decent match, but
then you have to rig the same for all the other bands..
IE: the Cecil method..

Quite so. And there is no "vs." here. Just two different ways of looking at the same physical phenomena.

I made a 160m loop out of LMR400, using the capacitance of the inner-to-
outer conductor to resonate it. Made it two turns and wound a gimmick
match out of flat 4-wire phone cable onto it to fire it up. Very narrow,
but reasonably effective. Better than a hamstick, I think. It's about 3
feet in diameter.

My normal 80-10 meter set-up is a hamstick horzontally off the balcony
rail. The rail backs onto a stucco wall with underlying mesh, so the
"ground" although tilted sideways is vastly larger than the average car.
I'm going to try a screwdriver there because I like the idea of being
able to change bands from the operating position instead of needing to go
outside in whatever weather is happening at the moment.

Yes, my 160m loop is almost too narrow for SSB.

Hi Dave,

Radiation resistance for a 1 meter loop at 1800 KHz is 23 microOhms.
If I were to interpret your BW to be 2 KHz (an antenna Q of 900); then
the Ohmic resistance would be 0.0225 Ohms (0.002 Ohms/foot). This
resistance is on par with #13 wire which has considerably less surface
area than the LMR400.

The added resistance resides, undoubtedly, in connections (or maybe
the gimmick); and if you drove it out, you might find your loop
suitably more efficient for CW-only. Unfortunately, it might become
an arc-gap transmitter.

As an aside, I can't visualize the gimmick's relation to the
inner/outer conductors. You have any close-up pictures?

I have, quite serendipitously, found a radio with a built-in auto tuner that will match my Van Gordon All Bander with its twinlead feedline and a 4:1 balun. So far, I haven't discovered anywhere that it won't tune, but I don't use 160 meters...

The rig is the Yaesu FT-890AT from ten or fifteen years ago. I was blown away after trying it just for a lark and finding it operable everyone I chose to operate.

>>The test jig will contain a Network Analyser.
FWIW:
Rhode+Schwartz, Agilent, Anritsu and others would be happy to tell you
how to do it (when you spend $100K on the core of the measurement
system, the field application engineers are more than willing to spend a
few hours or days figuring out how to make your measurements)

Does your test jig have to make all the measurments "hands off"? or is
reconfiguration of the test port cables between measurements ok?

If the former, you need a 16 port measurement system with a suitable
relay box.

>>
>>Where I have a split path or differential measurement, do I always have to
>>use phase matched and batch matched cables?

In theory, you'll be able to calibrate out all the various port
configurations. If you're using one of the newer PNAs, this is pretty
straightforward with an automated script. You'll connect your cal
standards to the ports you need, configure your test jig relays, run the
cal, store the cal configuration, go on to the next.

Then, when making the measurements on the UUT, you just do something
along the lines of:
For each measurement
Configure test jig
Load Cal set corresponding to configuration
Make Measurement
Save data
repeat

>>
>>Does my test jig switch calibration loads between ports? The cal load being
>>an open, a short and a load.

It can. This is sort of like what an "E-Cal" box does. You'll do a
one-time calibration of your cal stuff. What kind of performance do you
need?

>>
>>Do I get the paths the same by using phase matched & batch matched cables,
>>and then do a vector gen to save a 'footprint' of the test jig when it is in
>>a known good
>>state?
>>
Sort of.. there's a bit more to it, but essentially that's what's done.
For a full bidirectional two port measurement, there's potentially 16
calibration terms for each frequency.

>>How do I minimise errors introduced by imperfections in the test jig? I am
>>looking for the test jig to measure the absolute SWR and insertion loss of
>>the RF switching unit, using S parameters.

To what precision do you need to know these things. 20dB return loss is
a heck of a lot easier than 50dB. 0.1dB insertion loss is harder than
1dB. What sort of isolation do you have between ports of the UUT and do
you need to measure it. (i.e. is the isolation good enough that you just
need to check it, and after that, you can ignore the ports that aren't
connected, or do you have to do a full N-port characterization)

Sir Cranston: One answer to your question is "it depends". It depends on the radio and it's ATU. My old TS-940S(AT) autotuner successfully handled several Field Day G5RVs which had gawdawful high SWRs on most bands.

The direct answer to your question is that according to it's published Kenwood specs the autotuner in the TS-840SAT can't handle SWRs above 3:1 which immediately precludes it's ability to match G5RVs on most bands. As Mark put it it's a "line flattener", not a real antenna tuner. Annoying marketing gimmick.

My FT-847 doesn't have an ATU which is OK with me because I use an external LDG AT-11MP ATU which I'm convinced will match almost *any* antenna to the radio. Did a proper job of matching couple more recently used G5RVs. The MP is out of production and has been by replaced by the even better AT-100Pro. A couple hunded bucks well spent.

A Slinky dipole is an excellent illustration of the fact that we use a lot more power than we need to. As some folks have pointed out, most of the power you send to it ends up as heat. As others have noted, you can still talk to lots of stations with it. If everybody would use one, it would drop the QRM level a lot.

FWIW, I have an ICOM Pro II, an Ameritron ALS 600 and a Palstar AT-
AUTO Tuner feeding a True Talk 102' G5RV. Just for the heck of it, I
took the amp and Palstar out of line. The Pro II tuner tuned all bands
from 80 to 6 with no problem. You might want to consider adding 6' or
12' of coax to the transmission line. Sometime that will do the
trick. GL es 73, Tom K3MOV

Some radio tuners will tune many loads..
But... I'd be kinda paranoid to use it as such if the
loads are far off the 50 ohm path. In some cases
the tuners can run real hot in those cases, and
I'd be afraid to whack it out.. Not a cheap fix for most
of those built in tuners.
But thats just me.. If anyone else feels lucky, have at it.
Myself, I never buy the built in radio tuners. I'd rather
have one outboard if I needed one. In most all cases,
my antennas are ready to go as is..
IE: all my home/portable antennas are resonant/tuned,
and my mobile is already matched by it's own devices.
So for me, I rarely would need a inboard tuner.
I'm still using a IC-706mk2g for most of my radio play.
No tuner in it.. Ditto for my old TS-830.. Course, the
830 will match a pretty wide spread just with it's
loading control. A 3:1 match is no sweat to it most
of the time..

I'm not sure it is as wide as 2khz. LIS, it's not really suitable for
SSB. It's OK on CW, though.

> The added resistance resides, undoubtedly, in connections (or maybe
> the gimmick); and if you drove it out, you might find your loop

I'd not recommend it for low power.

Look at Ted Hart's loop design in the old Antenna books. I sort of
patterned it after that. The 80 meter 1-turn loop is a bit bigger and,
of course works a bit better. Don't get me wrong, these were test-of-
concept antennas and I don't use them for my working antennas. If I were
to build a working loop for 80m, I'd do it out of 2-inch copper pipe and
make it as large as practical.

Message-ID: <c5c3c$46eafa66$18d6b40c$17868@KNOLOGY.NET>
Source record: 36431
Cross-posted to: rec.radio.amateur.antenna,alt.internet.wireless

I've posted a picture on >alt.binaires.schematics.electronic<
to an effort to help me get a better understanding of an antenna.
It is a 2.4Ghz antenna about 18" long
The driven element is a copper ribbon 0.2" wide by 0.032" thick.
The copper ribbon forms a loop about 2" wide by 0.625" tall.
The gap in the ribbon would be 0.020", but note; in the pictures
a moon shaped piece has been cut from both ends. I think this
moon cut effectively make the gap look larger.
The total coax length is 2.350", the shield a bit shorter at 2.08".
There are 4 toroids on the coax. These are under a piece of heat
shrink, so I have no idea what material they would be.
All element spacings are all equal and element lengths are within
.030" of each other. I think they were designed to be the same but
manufacturing tolerances made the differences. The reflector is longer.
So now what can the group tell me about;
Driven element impedance
the gap
coax length impedance transformation
the 4 toroids
Thanks for the help, if you need any other details let me know.
Mike

Could anyone help me on what is the best spray/brush on sealer to use on my vertical antenna resonator?

I have home brewed the 80m resonator for an elderly Hygain AV-18VS, but need to weatherproof it.

Is clear polyurethane from the paint shop OK to use?

Is there another more suitable commercially available sealant?

I would appreciate any help or knowledge please.

1414. 10 meter antenna and radiation angles

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-15 00:18:27 UTC

Hi All. I will be getting my General Class license in the very near future I hope. Of course, they got rid of CW after I finally had 5 WPM mastered. :-)

I live in New England and a friend of mine lives about 300 air miles away. He has a 100 foot tower and it's amazing to see him work 20 meters. He also mentioned that he is finding 10 meters is opening more and is having luck there also.

Unfortunately, all I have access to at this time is a 25 watt 10 meter rig. For my first HF antenna, I would like to be able to communicate with my HAM friend as a priority, with any further contacts a bonus. He recommended a full wavelength dipole set up as an inverted V and experiment with wire angles. I know the inverted V is much more omni directional than a flat dipole.

So the antennas I have considered which I hope have the proper take off angles are:
Inverted V
Moxon Beam
10 meter extended double Zepp (low radiation angle?)
10 meter vertical loop (experiment with loop angle and feedpoints)
Some type of sloper (dipole, end-fed, delta loop type?)

I'm hoping someone out there has had some luck with medium range consistency (300 miles in my case) at 10 meters. I have a fairly large yard but it is heavily wooded. The ground ranges from rich loom to solid granite. A 44' EDZ is possible but definitely won't be easy, although I will certainly make the effort. I also have a 10 meter yagi sitting in pieces but if you think that may work, I will have to suspend it from trees in a fixed direction.

Thanks!

Been quite a while since I've been on 10M, but I think 300 miles might
be a little tough. Too far for groundwave and I think a little too
close for E skip. Heck though, give it a try!

1416. Coaxial cable ExtraFlex 9096IIA ?

Newsgroup: rec.radio.amateur.antenna

Hi,
I need a low-loss flexible coaxial cable. Radio Works
(www.radioworks.com) sells the following model, which seems to fit my
needs:

ExtraFlex 9096-IIA (a flexible version of LMR400)

Did anyone try this coaxial cable? Are the specs as good as announced
on their web site? What are your comments?

Yep. Too close for local, too far for skywave. But hey, ya never know.

Solar activity is way down, it isn't like the 70's ...

This is similar to the Davis Bury Flex. I have not used the 9096 but have used the Bury Flex. Measured at 440 mhz it seems to meet the db loss specifications. Measured 4 pieces about 100 feet long and got the same results. Just under a 3 db loss including the connectors.

http://www.davisrf.com/ham1/coax.htm#buryflex

You will have to trade that 10 meter rig for something that will work 80
meters or 40 meters. While the band may open sometime for that distance,
it is too far away for ground wave and maybe too close for sky wave most of
the time. No antenna that can be put up by most hams can help you reach
that distance 99.9 % of the time on 10 meters.

300 miles is close to NVIS propagation and is
very unlikely on 10m at the present time.

If somehow you can sell that 10 m rig and get any kind of old all band SSB transceiver, you can work your buddy 99% of the time on 75 meters with a simple dipole. That's what 75 meters is made for. You can sit and talk for hours, armchair copy. And when he isn't around you can talk to others, you can't do that with what you are trying to do on 10 m.

IF super intense Es is going on (Usually in the summer, with
maybe couple times in Winter Solstius (xmas-new years), MAYBE -
but even this is a stretch! As stated, better 80-40 Meters, and BTW, IF
you should get THAT short skip on 10 (400 miles, or LESS), then bet 6
Meters is open! , but
then, I digress: Good Luck-- Jim NN7K

Hi Denno

The greatest quality of HAM radio is your being able to experiment with
about anything that pleases you. It is so unlikely that you will ever be
satisfied with audio communication with your buddy 300 miles away on ten
meters, that you might consider using Skype for that ONE contact and set up
anything that seems interesting to you for ten meters. It wont take long
for you to know alot about what antenna is best for you.

Jerry

With 100W, your best bet is probably 40 meters. People on 75 tend to run
some power.

The lowest point of the sunspot cycle is probably not a good time to
be using a 10-meter only rig -- while you're getting your General,
save a few dollars and get an all-band HF rig; there are plenty of
used rigs on eBay going for a few hundred or less. That will give you
the ability to work some of the bands that are a little more useful
during low sunspot activity.

You can always put up a simple 10 meter dipole, but I wouldn't obsess over trying to make 10 meters work at this time, except for scattered general communications, rather than trying to hit one single ham at 300 miles.

You will not get a consistent path on 10m of 300 miles without some
pretty expensive antenna hardware and high power. Just cannot be done.
You'd actually get off cheaper trying to do it on 2m SSB (which would
probably work OK if you stacked two yagis one over the other and fed them
with a good amp). Your friend would have to reciprocate, though, as
these forward scatter systems are on the edge at best.

Seriously, what you need for that distance is a wire antenna for 75 and
40m. And 160m if you can do it. They don't have to be all THAT high,
though I'd try for about 50 feet if you can. Use 40m during the day, 75m

during the evening and morning and 160m at night. As the sunspot cycle improves, you'll find that 75 and 40 between them pretty much cover the distance, day or night.

How about moon bounce? :-)

Which reminds me of something that nobody seems to
have mentioned. If a QSO is the only goal, satellite
communications should work well if not too crowded.

Yes, you all pretty much confirmed my suspicions. I may try to set up
a dipole low to the ground NVIS style, but I know it's probably a
waste of time. I have a great time experimenting with shortwave
antennas (although my neighbors are going crazy wondering what I'm
doing) and haven't had much luck on 10 meters there, either.

My friend's setup is doing incredible things with 20 meters, but
they're all 1200+ miles away too.

I have a beautiful old Kenwood HF rig that I'm preparing to set up
now. Guess I had better start thinking about lower frequency
antennas.

Thanks for the advice, it is much appreciated!

Depends on the type of satellite. LEOs will give a pass time of about
10 minutes per station and the birds coverage would need to overlap both
stations, so QSO time would most likely be 5 minutes or so. Using the
OSCAR 10 types give more time, but add complexity. Besides, I don't
think you can get by with a monoband (10M) radio...uplink and downlinks
are on separate bands. Packet works using the ISS as a digipeater (2M
though)...still short pass times :(

With one of the higher birds at apogee, that might actually be a good
solution.

Oddly enough the really big news is the "room temperature RF
superconductor plasma device. Heck, room temperature plasma is a kewl
trick itself. Fritz would be hugging himself in happiness!

But I do have to thank you for the link, because in further research I
found this little gem:

http://montalk.net/notes/potential-fields-primer

Those of us who are ever ready to suspend disbelief should be able to
spend days at the site, coming up with new science to confound us
skeptics!

I have built several coaxial dipole antennas in the past with great success. What I like about this antenna is it is broadbanded. If you design it using the center of the band of your interest, for the most part you can cover the entire band without retuning. The problem I have always had with this is the antenna is somewhat fragile. I have used plexiglass squares to secure the center of the antenna and taped nylon fishing line to the legs for more strengh. Any one with more ideas? These are mostly useful in the HF range. You can find the info on designing these at http://www.amateurradios.info and other places on the net.

Hi Bill,

I use 4 wire cage designs for 80m (as an inverted vee) because bandwidth is inverse to the length/diameter ratio, and a single wire has a bad L/D on the lower frequency bands. A single-wire 125' dipole made from #14 (0.071" OD) has a L/D of over 20000:1 while a 4-wire 24"x24"cage (effective dia = 8") has a L/D of 190:1.

If cut for the middle of the band, VSWR is just a touch over 2:1 at 3.500 & 4.000 MHz. I make spreaders from 1/2" thinwall PVC tubing & crosses (24"x24"). I use #14ga 168-strand soft-drawn copper wire but smaller wire could be used w/o much sacrifice in strength. A handy online calculator is here: http://www.smeter.net/antennas/dipcage2.php

A few photos of my home QTH antenna: http://tinyurl.com/2puwx5, the apex at about 50' in a tree. A bunch of photos of my latest FD setup: http://tinyurl.com/38v9wn, the apex at 35' on a homebrew tilt-up/rotatable mast. I use a choke balun at the feedpoint. All parts came from Davis RF: http://www.davisrf.com/ because they have good prices and stock my preferred compression insulators.

You seem to be remarkably ignorant about the containment of the fields
within the coaxial cable, OM. Neither within the configuration of the coil
nor in straight line sections of coax do the wanted signals contribute to
any
external fields (save, perhaps, in the case of leaky feeders).

The wanted currents just do not form any magnetic fields in the coil to be
cancelled out!

Such ignorance would be an absolute disgrace if it was expressed by, say,
one
charged with the training of all candidates for Radio Hammery in Britland!

So how do YOU think the magnetic field is "contained"? You are keen to critise other's explanations, let us see yours.

Also, if there is no magnetic field do to the "wanted" (signal) currents, why are losses in baluns an issue? (That is one of the practical items I hinted at.)

So how do you think the magnetic field is "contained" in a coaxial cable?
You are keen to criticise other's offerings but offer nothing yourself.

This discussion is about the comments.....

" Conversely, the (wanted) signal
currents (on the outside of the inner and inside of the outer) cancel out
the magnetic fields they form in the coil and thus don't see it as an
inductor."

.....which discuss non-existent fields.

The containment of the wanted fields within the coaxial cable is another,
different,
discussion.

By all means start another thread to discuss whatever cranky theory you have
about
those contained fields, but I think that you won't find anyone to support
your
pet theories!

As to "critise (sic) other's explanations", I have not criticised any
other's explanation
about the fields _WITHIN_ the coaxial cable, so your challenge is a Straw
Man!

It is always possibly that I have misunderstood what you wrote, so, as the
discussion
is very much about what you wrote, perhaps you could explain your
comments,.....

"Conversely, the (wanted) signal
currents (on the outside of the inner and inside of the outer) cancel out
the magnetic fields they form in the coil and thus don't see it as an
inductor"

.....in a manner that is unambiguous? Then, perhaps, go onto another thread
to discuss your theory that the contained fields differ in operation to all
of the standard texts on the subject?

So you don't have a better explanation, fair enough why didn't you just say
so?

Until you come up with something better, mine seems to be the one in game.

Once again Chippenham is a Foot in Mouth, technical knowledge exclusion
zone.................

By the way, I suggest you think about losses in the core of
baluns.....................

So, you are unable to explain your assertion and resort to rather silly and
infantile
interjections in a forlorn attempt to divert attention?

You said the following.....
" Conversely, the (wanted) signal
currents (on the outside of the inner and inside of the outer) cancel out
the magnetic fields they form in the coil and thus don't see it as an
inductor."
.....which discusses non-existent fields.

Unless you now justify your own remarks you will lose face.

No amount of bluster, spin-doctoring, side-stepping, bullshitting and
downright lying
from you will hide the fact that you are losing face.

I will be more than happy to reply with an explanation once you offer a
first explanation
of yours of your assertion quoted above. You made an assertion, I replied
with an assertion.
You want an explanation from me, you start with your own explanation

Over to you.....

(The clock is ticking, your face is reddening)

Hi Mike,

That is a very complex subject. I would go to the library and check out a good book on antenna theory. "The ARRL Antenna Book", while aimed at amateur radio operators would still provide you with more theory than you're likely to even need to know. An excellent book!

| I've posted a picture on >alt.binaires.schematics.electronic<
| to an effort to help me get a better understanding of an antenna.
| It is a 2.4Ghz antenna about 18" long
| The driven element is a copper ribbon 0.2" wide by 0.032" thick.
| The copper ribbon forms a loop about 2" wide by 0.625" tall.
| The gap in the ribbon would be 0.020", but note; in the pictures
| a moon shaped piece has been cut from both ends. I think this
| moon cut effectively make the gap look larger.
| The total coax length is 2.350", the shield a bit shorter at 2.08".
| There are 4 toroids on the coax. These are under a piece of heat
| shrink, so I have no idea what material they would be.
| All element spacings are all equal and element lengths are within
| .030" of each other. I think they were designed to be the same but
| manufacturing tolerances made the differences. The reflector is longer.
| So now what can the group tell me about;
| Driven element impedance
| the gap
| coax length impedance transformation
| the 4 toroids
| Thanks for the help, if you need any other details let me know.
| Mike

And so, as the Sun sinks slowly in the West, Brian Reay M3OSN, director
of the RSCB, runs away with his tail between his legs. (_ONCE_ again!!!!!)

Perhaps it is no wonder the gangrenous degeneration of standards as
represented
by the M3/CB Fools' Licence scheme when the chief L.I.A.R. of the RSCB (a
commercial
book seller that vaunts itself, falsely, as the representative of all Radio
Hams and Short Wave
Listeners) is so mediocre both in his technical knowledge and in his
standard of debate?

Perhaps it is no wonder the decline in social behaviour when he who is
charged with the
education of youngsters demonstrates such an infantile abusive role model if
ever he
is challenged?

Sic transit gloria Mundi.

It's apparent to me that it can't appear that large because it's 4 strands of 14ga wire instead of a 24" diameter cylinder. I obtained the 8" figure from the calculator program at: http://www.smeter.net/antennas/dipcage2.php. I don't know how the effective diameter was calculated.

> Doesn't soft-drawn copper stretch like mad?

I was told by the CSR at Davis RF that it's soft-drawn but I expect it's hard-drawn -- an unscientific stretch test in my workshop appears to confirm this. Over a 12 month period, a 12ga single-wire 80m dipole (with choke balun & RG58 feedline) did not noticeably stretch. Also consider that in my case, the cage dipole is in inverted vee form, so there's no concern about wire stretch caused by the heavier LMR400 feedline & balun weight. Also, it's 4 strands of 14ga wire instead of one, and the spreaders don't add much weight.

Hi Mike,

It is simply a function of the mechanical connection of the line at
that point (the inner conductor needs the cut-out and the shield has a
closer point of attachment).

> So now what can the group tell me about;
>Driven element impedance

50 Ohms.

>the gap

the distance between the closest points of contact before the line was
installed - i.e. the thickness of the inner conductor's insulation
(true for absolutely every antenna built).

>coax length impedance transformation

Not sure that matters if in fact it has been designed to be a Z
transformer. If so, then you have one of several dimensions possible
n/4 wavelength or n/2 wavelength where n is odd.

>the 4 toroids

Decoupling.

I had to go back and look at the picture, but that's interesting, the
cutout
makes for a good fit for the mechanical connection to the coax.
And I'll use that,
> "i.e. the thickness of the inner conductor's insulation"
for the gap in the antenna I'm building.

Any idea how to slove intermod problems at repeater location, very close (150 meters) to VHF repeater antenna is located FM-TV tower with 7 strong FM channels, nominal power is from 5-10KW + antenna system gain. Bad thing is that combination of 104.7 MHz + 145.7 MHz (repeater tx) - 105.3 MHz = 145.1 MHz (same frequency for repeater input) !

There is 3 +3 cavity duplexer pass/reject type and professional type of vertical dipole with 0 dB, I`m sure if notch cavity can change this problem or installing high quality FM Trap filter to existing setup.

Tnx for any help !

Dear "Lex--Lutor" (no call sign):

1. In North America, the frequency spacing between FM broadcast transmitters in the same area is usually 800 kHz. 105.3 MHz - 104.7 MHz = 600 kHz. Are you sure about the two FM broadcast frequencies?

2. IM is produced from a nonlinear response in something. The odds are strong that the 145.1 MHz signal is being produced in one or more of the three transmitters - most likely one or both of the FM broadcast transmitters. Adding filtering in your system will have no effect if the IM is produced outside.

3. It is a good idea to perform a classical IM analysis (up to at least seventh order) that involves all seven of the broadcast frequencies and to use the analysis to select a repeater pair that does not involve an IM frequency.

4. Theoretically, you could place a filter or isolator in the broadcast transmission lines.

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

1459. Ratio A/B

I am trying to teach a test equipment class. In the course of explaning the purpose of the input A /input B ratio setting of a fequency counter I explained this as using an external time base where the counter will read events A per event B. I have been told I am wrong but so far noone who has said I was wrong cares to give a better explanation. I freely admit that I have never had call to use this feature of a frequency counter. The example that I gave was that if the output of a magnetic trannsducer that picked up pulses from a flywheel was coupled to A input then the proper time base could be calculated and applied to the B input so the display on the counter would be in RPM. Is this not correct?

The intermod could be arising in any number of locations. Some are
probably filterable, others probably aren't.

You could be getting intermod from:

- Mixing of the 2-meter TX with commercial FM, in your 2-meter TX
finals (FM "coming back down the cable"). The best solution to
this would probably be a ferrite circulator/isolator, located
between your TX output and the duplexer DX input... this will
divert any RF coming back down through the cable and duplexer into
a dummy load before it reaches your finals and mixes in.

- Overload of your receiver by incoming commercial FM - you might see
intermod or desense from this. You could try a notch filter tuned
to the commercial FM signal, or a high-pass filter to attenuate the
whole range below 144 MHz.

- Intermod created in the antenna system itself, due to some form of
nonlinearity (corroded connections or joints, presence of dissimilar-
metal junctions where plugs and jacks interconnect, etc.). In some
cases you may be able to get rid of this by cleaning up the
antenna... e.g. eliminate nickel-placed N/UHF connectors (use only
high-grade silverplated connectors), make sure that all cable
connections are tight and weatherproofed, check all bonding
connections to make sure that they are solid and not corroded, etc.

You can't get rid of this latter sort of intermod with a filter, as
it's being created outside of your electronics and the resulting
intermod signal is right on the frequency you want to receive.

Screening the antenna from the commercial tower, or placing your
antenna on that same tower but directly above or below the FM
antennas, may gain you enough reduction in commercial-FM signal
strength to bring the intermod to within tolerable proportions.

Hy,

Yes I`m sure, in EU we have RX feq - 600 KHz for TX on 2m Ham band, for
PMR band it is RX + 4.5 MHz for TX ..

>
> 2. IM is produced from a nonlinear response in something. The odds are

I made a spectrum check at RX side after duplexer, there is lot of junk but
145.1 is clear, than I put repater in TX mode with spectrum connected at
duplexer RX port and you can see a modulated carrier - 95 to -90 dbm. In
demodulation mode (Wide) you can hear mixed program of this two
radiostations. I repat this test few times on two different spectrum
analyzers with and WO external attenuators in input line with same results.

I`m sure where is source of IM, repater antenna, coax line, or duplexer?
Maybe all 3-parts togother since duplexer is not Hi.quality, it is made from
aluminium cavity and Cu plunger, no sliver plating, RX and TX side are
separated so there is no good DC connection !

Hello Bill,

I can understand that the coax dipoles you built are somewhat more broadbanded than a simple dipole. However,
I suspect that you are unaware of the reason for the broadbanding. Sorry to tell you, but it is achieved only
by the resistive losses in the coax, and not by the reactance obtained by the two sections of shorted coax, as
incorrectly stated in several published articles.

I have made extensive measurements and calculations that prove my statement above. I have reported these
measurements and calculations in both QST and in my book 'Reflections'. The QST reference appears in the
Technical Correspondence, September 1976 issue, and in Chapter 18 in Reflections. You can read Chapter 18 from
my web page at www.w2du.com.

On the other hand, realistic broadbanding, without the loss introduced by the resistances in the coaxial
dipole, can be obtained by the 'cage' dipole, using several parallel wires separated by spacers, as mentioned
other posts appearing in this thread.

Hi Walt et al,
I was going to point out the same flawed thinking. I believe Frank Witt also published the analysis for the flawed reasoning of the bazooka stubs correcting for the reactance of the dipole off resonance. He also published coaxial stub designs that did work in QST and several of the ARRL compendia. It is amazing to me that the bazooka is still used given the alternatives. One sight where thay are sold claims more gain too!

Seems about right me. Depending on the particular counter you could
possibly have A and B reversed. In general it will give you the ratio
between two frequencies. The way my counter works in that mode, B
replaces the timebase input to the decade divider, so that it's really
the frequency ratio A*(10^R)/B, where R is setting of the decade
divider.

Cheers,
Tom

Hi Jimmie,

You desire a reading in RPM (and we still have a frequency counter where you could end up with a time interval counter if you invert relationships). Assuming the timing pulse indicates one revolution, it then requires a time base of one minute. This would be the conventional explanation and it would render an accurate determination provided your source doesn't drift during the sample period.

Counter naming conventions usually include a "trigger" and a "gate." Your A/B connectors and panel switches should indicate these conventions somewhere.

The time base input needs to go to the gating input (replacing the internal time base); the pulse being displayed in RPM goes into the trigger input. The gating input can either be direct, or through the internal divider. You may have to attend to details of gating pulse shape (square or otherwise which can really upset the applecart), and gating pulse trigger (edge or level). As you can see, the clock should be for two minutes for a square wave, level triggered gate; a one second pulse with a longer repetition rate providing you select the correct polarity; or if edge triggered, any pulse with a repetition rate of one minute. Mixing up the three can lead to confusion (and I may have confused this at this hour, others will no doubt clear the air if I have).

However, RPM applications are rarely stable, and more commonly you desire a quicker indication than once a minute. Further, the internal (usually decade) divider does nothing to satisfy these common complaints. It serves as a convenience if you lack a 0.016... Hz standard and instead have a 16.66... KHz xtal.

You can speed things up by having triggers arriving every, say, 60 degrees instead of every 360 degrees, not very difficult for slow machinery (cars do it all the time for Tachs) and it can clear up scaling (you are back into ordinary decimal time bases). Accuracy is rarely sought in these situations as machinery is often quite variable and high resolution is rarely demanded. If, on the other hand, you do want increased accuracy; then you abandon frequency counting and go to

interval counting instead - and then do the inversion outside the box.
This commonly occurs below 100 Hz to 1000 Hz.

Using a Strobotac is a far more engaging demonstration of frequency determination for students. This is especially so for a fan running in a dark room.

While on the subject of freq counters I bought a Systron Donner 6152A at a
hamfest about a year ago paid 6$ for it. I had expected it to be junk so I
just got around to plugging it in and it all seems to work. Is this usually
considered a good instument?

Hi Jimmie,

More counter than you can get anywhere for $6, certainly.

Mid 60s vintage, with limited frequency range and resolution. A certain amount of fussing around to extend it and perhaps issues of sensitivity, but still quite useful. I calibrated a ton of them (SDs), but I don't recall them being dogs - just not modern. Freq counter design is fairly straight forward once you get past those from the late 40s through early 60s (they REALLY qualify as museum pieces).

If you want to really qualify it, it should have a double oven xtal control. Single oven would be good. I would guess this model hasn't any oven at all and is simply tempco (although, that may be sophisticated in its own right, or possibly just xtal selected - the lowest grade of lab reference).

I think you would be better off with a good vertical or ground plane.
There is not much point in running the typical "NVIS" antenna on
10m. There will be very few cases where the signal actually goes
straight up and down. Just doesn't happen on 10 much.
A low dipole will be the pits for most of the usual paths you
would work on 10m. It will be semi ok working skywave across
the country, but the good ground plane would likely be even
better. Probably by several db...
The ground/space wave with the low dipole will be half useless,
and much of the activity you will find on 10 will be fairly local at
times. In this case, the GP will smoke the dipole.
I used to hang out on 10 a lot several years ago, and if I had to
choose a single simple antenna, I'd use a good vertical or ground
plane as high as I could get it.
This will give the best overall performance for all the types of
paths you will likely work on 10m.
If you did get some short skip going, which is more likely
to be back scatter, or aurora, etc, the vertical will still do
the job as most will still be at a fairly low overall angles, unlike
the typical NVIS on 80m, etc.. There is very little true NVIS
on 10m. The skip zone is too long, even when it's short for
10..

Most of the newer ARRL Handbooks have a section it them that give the
differant bands and how far they are good for during the day and night.

For example:

3.5-4.0 MHz (80 m)

The lowest HF band is similar to 160 m in many

respects. Daytime absorption is significant, but not quite

as extreme as at 1.8 MHz. High-angle signals may

penetrate to the E and F layers. Daytime communication

range is typically limited to 400 km (250 mi) by groundwave

and skywave propagation. At night, signals are

often propagated halfway around the world. As at

1.8 MHz, atmospheric noise is a nuisance, making winter

the most attractive season for the 80-m DXer.

Hi Bob,

Listen for 5 minutes every hour on each band you typically have an
opportunity to work a QSO.

Keep an activity log over a week to 10 days. Repeat this daily cycle
every 6-8 weeks over a year. Repeat this bi-monthly cycle every
couple of years for slightly more than a decade. You will have your
own rule of thumb.

Start now and you won't need theory or anyone else's book. If you
make a chart across time, you may see periodicities and become an
expert. They will conform in general to what may be found in the
books too - but your charts will be tailored for you (the hardest part
of theories, and the most useful bit of knowledge not found in books).

Even 10 days work will tell you more than a book or theory.

I am going to be replacing the 74141 nixie drivers. I thought as long as I
was in there I might replace the first 7490 decade counter. Is the 74LS90
better? T he reason I want to do this is the counter starts going haywire
if I put in more than a 30Mhz signal without switching over o the prescaler
input. I was thinking this should be good up to about 50Mhz.

Here are some useful notes on W6EL's program:
http://www.mdxa.org/w6elprop.html

It is contended that the W6EL program only uses the MUFs at the end points
of the path. For paths of something like 7 Mm or more this can introduce
large errors. Even the old, old graphical techniques used ionospheric
properties along the path.

Ionospheric propagation is such an interesting subject that I am not able to
understand why ND9B would not wish to "get deep in(to) propagation theory."
The ARRL's Antenna book has a useful and easy-to-read section on HF
propagation.

Hi,

I'm new to amateur radio, and am looking to build my first antenna for
the 2m band. I intend to build the one at
http://www.qsl.net/iz7ath/web/02_brew/12_jpole/jp_eng.htm.
As this is my first, I have a couple of questions about it's
construction:

1) Can I use copper tubing instead of aluminium?
2) Are the tube diameters crucial?
3) The instructions seem to imply that I can use the longer of the
tubes to mount the antenna. Does this need to be insulated?
4) I'll be using the 2m band, max power 10 Watts, and a cable run of
no more than 20 meters. What sort of cable would be best fro the
feeder? (Ideally one that can be purchased from Maplin:
http://www.maplin.co.uk/Search.aspx?menuno=12276&MenuName=RF%20Cable&FromMenu=y&worldid=3&doy=18m9)

Thanks.

Thanks for that. I'm thinking about going with the design you gave.
I'm also guessing I'll need to tune the antenna using an SWR meter. A
lot of the ones on ebay (UK) are listed as CB SWR meters. Will these
be OK for the 2m band?

>manufacturer pattern plots to compare these antennas.

I put together a couple of NEC models for the G7-144 a year or two ago. If I recall correctly, this antenna is composed of three 5/8-wave radiators in a collinear arrangement (stacked one above another) separated by relatively short inductive loading/phasing coils. It has quarter-wave radials at the bottom and is fed at the base through a tapped coil.

I did two different models - one using shorted transmission-line stubs as the phasing elements, and another using lumped inductances. With the stub lengths, and the inductance values tweaked to give the correct current-phase relationships in the 5/8-wave radiating sections, the two models produced almost indistinguishable results in the pattern analysis, and a gain figure which matched the manufacturer's claims quite well. I can't claim that the models are precisely correct, but I'd guess that they're fairly close.

The pattern seemed reasonably clean... most of the energy went straight out towards the horizon. There were minor lobes upwards and downwards at an angle of around 45 degrees, as one would expect from a 5/8-wave radiator. I didn't see any systematic "squint" (up-tilt or down-tilt) in the pattern. The "donut" of the pattern was significantly shallower than that of a half-wave reference dipole... not s surprise.

I added a random wire down from the feedpoint to simulate the "RF on the outside of the coax or on the mast" issue, and found that there was little current and little effect on the pattern... according to the models, at least, the quarter-wave radials do a pretty effective job in decoupling the antenna from the mast and feedline.

I compared these results against those for another antenna design I've been considering for our repeater - a pair of "plumber's delight" copper-pipe 5/4-wave extended double Zepp antennas, stacked one above the other (about a quarter-wave separating the tips of their inner arms), fed in phase. The results were roughly comparable.

I've got the models on my laptop PC at home, I think... if I can find 'em I'll email them, and perhaps some results plots to you.

The biggest concern I have about the G7-144 isn't its pattern - it's some aspects of its construction. The one we're using went bongo after a few years up in the weather - the repeater began suffering from extremely severe desense - it was so bad as to render the repeater unusable unless you were within a mile or so of it. We temporarily swapped the Hustler for a simple J-pole and got back most of the performance.

When we tore down the G7-144 we found that the bottom end of the base-matching/feed coil was high-Z from ground. The construction of the antenna base depends on a heavy-gauge press fitting between two sections of aluminum to establish the connection between the base of the coil and the N connector, and about five years of weathering (in a fairly mild climate) had led to enough oxidation to allow the connection to go open-circuit at DC! I believe that there were also some connections which were done with ring terminals and rivets. The antenna actually worked, in the sense that it transmitted and showed a low SWR, but there was enough micro-arcing and rectification taking place in the oxidized connections to create plenty of broadband noise which was swamping the receiver and leading to many dB of desensitization.

Our chief metalworking guy tore the whole thing apart, and rebuilt the base with a better N connector and a pair of soldered connections between the coil base and the ground shell of the N connector. He also cleaned up all of the sliding-tubing connections between the radiators and phasing coils, roughened them up a bit, gooped them with a conductive anti-oxidant compound, re-fit and re-tuned them, then drilled through the tubing and riveted them together, and then used heat-shrink tubing over all of the phasing-coil connections. I think he believes in wearing suspenders, a belt, *and* duct tape :-)

We put it back up, and found that the desense was down to undetectable levels. It's been up in the air for 18 months now, with nary a problem.

We're going to have to move our antenna tower in a few years, and at that point we'll probably retire the G7-144 and replace it with either a stacked pair of EDZ antennas (homebrew) or a stacked folded dipole system (commercial). Both of the candidate designs use fully-soldered or fully-welded radiator construction... they're DC-grounded and would be free of sliding or press-fit connections which could oxidize and degrade over time.

Not really , go for a proper SWR meter suitable for freqs up to 150 MHz
Even better ,buy or borrow an antenna analyser . The MFJ259 is rather
popular ,but there are others as well.

Tom,

Most of those CB SWR meters are good for HF and probably 6 meters or
so. My experience is that they are highly inaccurate at best, and
often completely unusable on 2 meters. I lend my Bird wattmeter out
frequently for people doing installations because of this.

Of course, there are so many units out there it is impossible to say
with certainty that they won't work, but that's what to expect. You
don't what an additional unknown in building up a new antenna.

Hello,

I have just gotten my radio license and someone gave me an old hammarlund receiver that hadn't been used in over 25 years. I used a variac to bring up the power slowly, because I was told that the capacitors needed to be reconditioned. Everything seemed to work fine and I was able to pull in some transmissions with a random wire antenna. I don't have a transmitter yet, so I am hoping to just use a longer random wire antenna, laid along the attic until I can get money together etc. My question is probably dumb, but I was wondering if there is an "optimal length" for a random wire antenna for hf?

THanks for any help you can provide,

Joel Hainley

Hi Tom

If you really feel like not spending money on a SWR meter you might like to try the horrible but simple approach of making one out of a piece of RG213 with the PVC stripped off, and thin teflon wire pushed under the shield in the same mechanical arrangement of a SWR meter. A couple of shottkeys, capacitors and resistors and you can read VSWR on a multimeter!

I'd even venture to suggest that replacing the line section in a CB meter with this arrangement would yield a much more useful higher frequency device. (And use BNC's or N sockets...)

I can see you all cringing!

Cheers Bob W5/VK2YQA

Amen! I used to think anything above about 10 MHz went away soon after sunset. It was some erroneous "theory" that I had absorbed. In fact, some of my favorite 20m contacts have happened hours after sunset ... and toward places to the East, to boot!

1490. Re: Hustler G7-144 vs G6-144 vs dipole radiation pattern

Newsgroup: rec.radio.amateur.antenna

Source record: 36265

Thanks Dave.

That was an excellent post. It's interesting that I've read testimonials on eHam and other web pages that claim 15 to 20 years of service with the G7-144 with no complaints. Then there are some that have had some issues.

The G6-144 is a bit more attractive to me right now due to the lower price and being about 2/3 of the length of the G7. Interestingly, the G6 literature (available at http://www.dxengineering.com) says, "FCC accepted for Repeater application at 6db gain based on EIA Standard RS-239: gain compared to 1/2 wave dipole." I've never heard of antennas being "FCC accepted for Repeater application" before. So now I'm curious whether the G6 may be more rugged than the G7. At the very least there won't be so much aluminum swinging in the breeze.

I am looking for antenna for our repeater. We tried pressing a commercial antenna tuned for 155 MHz into service, but it just hasn't worked out as we have severe desense. Its mounting is also far from optimal. The calculated SWR at the antenna is approximately 1.8:1.

We were checking things over today and everything looks good when the duplexer is terminated into a 50 ohm load, but varying levels of noise exist at the RX frequency when the antenna is connected. It is definitely our system as the spectrum is clear when the repeater TX is off. It was too windy today to climb to the top of the grain elevator leg the antenna is on to check at the end of the hardline with a wattmeter and dummy load.

I like the idea of the G6 as it appears easy to handle and easy to mount. We are limited by the framework of the structure and we have to avoid having anything that would get in the way of the employees or jeopardize their safety. Also, it needs to be safe for us to work with as well.

The G6 appears to be two 5/8 wave radiators fed with Hustler's fiberglass encased coil assembly. I have seen that the antenna is about 10 feet tall, weighs about 7 pounds, and has a surface area of 1.4 sq ft. We can mount a mast easily on the structure that will support a lightweight gain antenna like the G6. A DB-224 would be nice, but it requires considerably more in the way of mounting and manpower resources to do it correctly.

Any suggestions are appreciated.

Must say that I second this, as the "sampleing" in MANY swr meters not
only DON'T read accurately, at VHF, but actually induce a "Impedence
Mis-Match" (and gives you a FALSE reading , at VHF) ! In fact, have
seen "Flat antennas, show some hideous SWR's " ! And, tho length is
of the antenna element is
the determining factor, you need a good meter if you want to minimize
the swr. As to insulating the J-Pole, BELOW the 2 vertical elements,
this shouldn't be necessary- and - keep in mind that this antenna wants
a Balanced feedline-, so, that your coax WON'T radiate! BUT- as you
probably will use (unbalanced) coax (No BALUN) that your coax becomes
PART of the antenna system ! But this should not present itself
as much of a problem, unless it lets RF into the RIG/Power Supply in
a quantity to cause problems in those devices! As to coax, use the
lowest loss you can afford, tho, again, in this instance, will mean
LITTLE! At 20 foot length, RG 58 should work fine! Just build it, get a
fairly good match to keep the rig happy, and enjoy! Jim NN7K

I imagine that there may be some such regulations for some of the
commercial or public-safety bands? Minimum or maximum gains allowed,
or cleanliness-of-pattern perhaps?

It sure sounds as if you've got a less-than-good connection somewhere.

We had similar problems after a while with one of our "American
Legion" J-pole antennas, which use an all-aluminum construction. The
radiator and matching-arm rods were originally mounted with
set-screws, but on this particular antenna the connection had been
reinforced with a spot-weld. Due to flexure of the rods in the
breeze, the weld eventually became brittle and cracked... and the
antenna immediately exhibited severe desense due to broadband-noise
generation in the cracked junction.

>Any suggestions are appreciated.

We're looking at some of Telewave's antennas, which I believe are similar to the DB-224 in their basic design approach.

I'd also suggest that you take a look at the copper-pipe EDZ design at http://www.tcarc.ca/public/2mdez.php, which would have gain quite similar to the G6-144, I think.

The folks who run this page seem to like this antenna for repeater service. Since it's a grounded, fully-soldered design (you can solder the balun-attachment points to the matching stub) it ought to be quite free of desense-causing corrosion/micro-arcing points.

I built one of these for our repeater system, scaled down for use as a remote-linking antenna for the 440 band. Seems to have worked out well so far. The only thing I'd do differently the next time I build one, is wait to figure out the actual shorting-stub and balun attachment points until the antenna is actually in place on the tower. I tuned it in a free-space situation, and the presence of the tower de-tuned it a bit (enough to notice on a meter, not enough to matter in practice).

Instead of using RG213 coax I would use a short piece of 75 Ohms coax
(here in the UK used for sat dish feeder) with air gap dielectric .
The 10 mm (3/8 inch) OD variety is particularly suitable .
Without removing the outer sheathing a bare or teflon insulated wire can
be readily pushed through.

Frank

Wouldn't you be concerned over presenting a slight Z bump of a 75 ohm
piece of material? I'll admit I cant see it making a huge difference,
but as one is building test gear it might pay to be pedantic.

I'd also be concerned that pushing wire into the air gap would lower the
Z in an unpredictable way. Pushing it just under the shield keeps it at
a reasonably fixed dielectric spacing from the inner conductor.

If it works however, then I won't argue!

I'll check the anticipated 'bump' with the MFJ259B analyser.
First connected to a high quality professional dummy load good for freqs
to 2 GHz (ex cellnet industry),thereafter with the homebrew SWR sensor
inserted,testing in 2 stages : First with just the short piece of 75
ohms coax (obviously having the braid connected to chassis at one end
only) ;Secondly with the wire pushed into the air gap.

This is a useful and interesting NG thread.

At one time, at least, the ARRL Handbook recommended something like 95 feet.
Way too long is better than way too short. For instance, my 75 meter dipole
receives OK on 20 meters. The 20 meter antenna is useless on 75.

My question is directed to the different grades K,L and M ,whether any
particular grade would give better RF radiation performance .
It could be that the grade with the highest copper content gives the
best performance ,although I doubt that it will be measurable.
J-pole antennas I am familiar with are all made of aluminium,but copper
is of course better long term in an outdoor environment and electrical
contacts are reliable following soldering.

I have made emergency VHF antennas from a hunk of 2x4 and two pieces of 3/8" aluminum grounding wire. Then I get a piece of mini8x (any 50 ohm coax will do), skin back the insulation until I have enough material to solder an alligator clip onto the center lead and one onto the equi-distant piece of shielding. I then drill two 3/8's diameter holes approximately 4" apart in the hunk of 2x4. Calculate the 1/2 wavelenth of the band you wish to operate on. Cut a hunk of 3/8" grounding wire to that length, straighten and then insert it into one of the previously drilled 3/8" holes in the hunk of 2x4. Cut another hunk of 3/8" aluminum grounding wire to exactly one half the length of the first piece and then insert it into the remaining hole in the 2x4.

Connect the coax to your VHF rig via the PL-259 that you soldered onto the end opposite the end with the alligator clips and plug it into your rig. Clip the alligator clip fastened to the center coax conductor to the longest piece of 3/8" wire (half wavelength) and the shield connected alligator clip

to the shorter wire protruding from the 2x4. Adjust the height of the two clips (should be even with one another) for the lowest SWR. Voila! You're on the air with an instant J-Pole antenna.

All of this can be enclosed in PVC plastic piping for use outdoors.

My recollection is that the basic difference between the various grades is the thickness of the copper walls. The thicker-walled pipe is what's preferred for outdoor/buried use and/or higher pressures (e.g. use on the supply side of a house's water-pressure regulator).

RF current flows only through the skin of a conductor... it doesn't penetrate very far into the body. One web calculator I found says that the skin depth of a 144 MHz signal in copper is around 200 micro-inches, or 1/5000 of an inch. If the tubing wall is much thicker than this, the additional thickness will have no significant benefit in reducing resistive losses.

Since even the thinnest-walled (Schedule M) copper pipe has a wall thickness which is about a hundred times more than the skin depth, there's no electrical benefit to using thicker-walled tubing (Schedule K or L).

Unless there's some mechanical reason to want to use the heavier-schedule tubing, I'd just stick with Schedule M - it's lighter, less expensive, and should be plenty stiff and strong for most applications.

Normally, a J-pole has parallel conductors at the bottom 1/4 wavelength, with one of the conductors extending above that 1/4 wave section for an additional 1/2 wavelength above that. That would be a 3/4 wave piece of wire and a 1/4 wave piece of wire. If I'm reading your description correctly, you're describing an antenna in which there's the 1/4 wave of parallel conductors, but then only 1/4 wave above that of the "unaccompanied" part of the half-wave piece. Also, do you not connect the two pieces of wire together at the end?

I've seen J-pole designs fed at the bottom end, and I've seen them with the bottom end shorted and the feed line tapped up on the parallel section, but haven't heard of one fed tapped up on the parallel section without the bottom shorted.

Cheers,
Tom

Try it, just as I described it. It works and works well.

No, the bottoms are not connected, but there is a version that works with that connection.

I have a Brand NEW SGC MAC-200 200 watt Automatic Antenna Tuner I bought for a project a couple months ago. The project was canceled and the tuner was never used.

This is a 200 watt Automatic Antenna Tuner that has inputs for 5 antennas. The tuner will either automatically find the best antenna or you can switch the antennas manually. The unit is about two months old and the one year warranty is still in effect. The unit requires a small 13.8 vdc power source. I will find one and include it at no extra cost.

This is a great companion for the SG-2000 or the SG-2020 transceivers. Click on this link for more information on this unit - http://sgcworld.com/MACProductPage.html - .

I paid about $269 for it and I will sell it for $239 plus 9.85 shipping in the lower 48 states. Alaska, Hawaii and International shipping is more. It comes in the original box with the manual. Please contact me at: - iamw7gsa@gmail.com - .

Thanks, Bill.

>
> Tam/WB2TT

Thats mainly due to the way it's fed though.
As far as receiving, the short wire is plenty long enough,
just needs a better match.
If you feed a random wire straight to the center pin of most
radios, it will work pretty well. Even a short one.
Course, I probably would prefer a longer wire vs a short
one if I had my choice, but it's not really critical for a
good radio.
This is kind of similar to taking a 80 meter dipole
and shorting together the coax at the radio end,
and feeding as a vertical for 160m. The receiver will
be fairly quiet in the normal 80m config, but will jump to
life once you change the feed system around.
As far as the original poster, I would use whatever
fits. Not critical at all if you are truly feeding it
like a random wire.
Also, if you just stick the end of the wire in the center
pin of the radio, you shouldn't need any kind of
tuner in most all cases, if the radio is decent.

I don't think so -- just the cost. Aluminum, which is less conductive than
any common copper alloy, makes fine antennas.

By the way, please refer to the copper pipe section at
http://www.homedepot.com/webapp/wcs/stores/servlet/ContentView?pn=Pipes&lang
Id=-1&storeId=10051&catalogId=10053 (I think I had the price/quality
expressed backwards in my original post.)

There are none I know of. However, commercial systems are licensed by
ERP, so I would suspect that the antenna gain figures must be accurate
in order to get the ERP calculations correct.

Go the cheapest way, as recommended above. You can't tell the difference
between the various grades without laboratory grade measuring equipment.
Surely no one receiving your signal could ever tell the difference.

Why is anyone worrying about the BPL thing? It is pointless to worry about things that you cannot change, even when detrimental to you. Worry is non productive.

There is simply no way in hell that the needs of .5 million folks will supersede the needs of 300 million folks. Sorry, but it just isn't going to happen.

Instead of fretting and whining, why not try to come up with work arounds?

For instance, digital phone is probably much more able to handle the BPL noise than analog phone. Get busy! <G>

==========
Ed , The subject is BPL and its interference to Amateur Radio signal
reception.
You probably already have changed to a digital phone to mitigate
interference from your own (amateur radio)transmissions.

Frank GM0CSZ / KN6WH in northern Scotland where (like elsewhere
in the UK) BPL or PLT is not on because of demonstrated interference to
the radio spectrum. Moreover it is commercially not viable because up to
98% of households can get broadband via the telephone line.

Frank GM0CSZ / KN6WH

And I think the latter is an important issue.

Ed, I feel that it's an error to frame the BPL question as "the needs
of .5 million superced[ing] the needs of 300 million folks". That
would be a valid way to consider the issue *only* if it were, in fact,
valid that BPL was the only (or best) answer to "the needs of 300
million folks."

The analyses which have been published so far suggest quite strongly
that the matter is otherwise. Although some BPL proponents have been
claiming that BPL is the answer to the broadband connectivity needs
of under-served rural users (after all, almost everybody gets power
from the mains, right?), I have not seen *any* BPL proposal or
analysis which demonstrates that this is econonically possible. The
mains-BPL technologies which could provide meaningful amounts of
broadband bandwidth require a repeater/amplifier at frequent intervals
along the power lines and/or RF-bypass devices around pole
transformers. The capital costs of installing so many amplifiers /
repeaters appear to be prohibitive.

It appears that technologies such as WiMax will be able to provide
greater amounts of bandwidth, to a larger number of rural customers,
at substantially lower cost, and (by operating in licensed or ISM
spectrum) can do so without polluting the spectrum used by licensed
users of the HF bands.

In urban areas, cable-TV providers have the edge in providing
bandwidth to well-served areas thanks to their extensive installed
wiring plant. The telcos (with DSL) come in second, but DSL's
bandwidth is limited enough in a lot of areas that the telcos seem to
be struggling somewhat. BPL, with even lower bandwidth-per-customer,
looks even less economically viable in urban areas.

So, it's not an issue of "the needs of hams, vs. the needs of everyone
else." Rather, it's more an issue of "the needs of hams, and everyone
else with a stake in HF, vs. the desire of the power companies to make
a few fast bucks."

And, as the ARRL has pointed out, BPL doesn't *have* to create
interference on the ham bands. Motorola has proven otherwise. It
is possible to create a BPL-based hybrid system (fiber or
over-the-air microwave to the power pole, then a well-notched BPL down
the low-voltage lines to the house) without causing interference on
the ham bands.

The power companies *can* do it that way, if they wish to... and if
they can make an economic case that BPL is actually a financially
viable business. So far, nobody seems to have demonstrated that, and
the models seem to suggest otherwise.

Actually, preventing the "tyranny of the majority" is why a lot of laws (and for that matter consitutional provisions) exist. Otherwise you could, to take an extreme example, advocate the speedy euthanasia of all people over the age of 80 (or choose your preferred small minority), on the basis that their health care consumes resources that could better be devoted to improving the life of those that are younger.

You, obviously, have missed the whole point of just how IMPORTANT
various digital communications over power lines is/are.

1) The power companies can read your meter remotely.

2) You hook your stereo into the power line in one room, you hook up
amplified speakers, to the power line, in various rooms about the home.

3) Your TV tuner exists in one room and monitors in various rooms about
the home control/grab the signal off the power line.

4) Your baby monitor ...

5) Your home security system ...

6) Your home intercom ...

7) Your phone ...

8) Your amateur rig resides in one room ...

9) Various other devices, existing now and coming into existence in the
future ... and, the capability of ALL these devices to interact with one
another provides for the imagination.

10) The complete list boggles the mind.

And, the internet was not even mentioned.

Regards,
JS

If that argument had any true merit ...

There are more horse owners in the USA than amateurs, the "tyranny of
the majority" should be limited and those owners allowed freeway access
with their horses (which, predate the automobile!); absurd I tell you;
the reason is blatantly obvious without explanation!

Anyone have any idea as to the probable performance characteristics of two whip 40" whip antennas mounted approx. six inches apart, and used for receiving shortwave, primarily between 6 MHz and 12 MHz? Would they be more receptive to a signal approaching f/b, as opposed to s/s? Just wondering... Hoping someone can offer some advice as to whether they would be in any way directional.

Thanks for any replies,

Dave

They would be directional at the frequency where
6 inches is 1/8 wavelength. :-)

Hey Cecil, thanks for the reply.

Hmm. So, correct me if I'm wrong, but from what you're saying they would actually have some directional characteristics at approx. 2.5 MHz. What if I angled them apart at, say, 45 degrees? That would, I think, put the tops about 57 inches apart, and the two whips at right angles to each other. Any ideas what that would do? Or, if I flattened them out in opposite directions? I need an ARRL Antenna Handbook, only I wouldn't know what to look up...

Do appreciate your reply. Gives me something to think about...

Dave

If they are simply in parallel, they would not have much directivity. But
if one were to be phase-inverted with respect the other, there would be a
strong null along the bisector of the line joining them.

The gain at 9mhz is on the order of -30dbi, though so you will need a good
receiver or even a preamp.

Aha! A strong (or deep) null! That's actually what I'm looking for. So, what would I look up to start learning how to set one up as phase-inverted? I have a copy of Joe Carr's Antenna Handbook (think that's the title), would it have anything on such a setup, do you think? What would I look for in the ARRL Antenna Handbook? Does this type of setup have a name to search on?

And yes, compared to my 110' longwire, the signal is miniscule. But I'm working on that.

Thank you so much, Dave, for this input. Now I have some idea as to what I am looking for, (I *think*).

Much appreciated.

Trying to phase two antennas that close together at that frequency range will be an educational experience at best, but more likely just an exercise in frustration unless you have much more patience than average. Such an array will be hyper-sensitive to everything. You might be able to fleetingly see a null after a lot of tweaking, but I seriously doubt you'll even get that. A tiny change in frequency, wiggling of the whips, or even movement in the vicinity of the whips will have a profound effect on any null you might see.

If a null from a small antenna is what you want, you'd have much better luck with a carefully constructed and balanced ("shielded") loop.

If that were true, we'd be in big trouble -- but it isn't.

Most of the several million (far fewer than 300 million) who might
potentially use BPL don't know what it is, don't know to ask for it and
might not even take it if it were offered. We 0.5 million are organized and
we know exactly what we (don't) want. An organized campaign usually beats a
muddled mob.

As long as we maintain a coherent strategy of opposition, we have the effect
of many times our number.

Found my copy of Joe Carr's Practical Antenna Handbook, and re-read the section on phasing verticle antennas. I believe you. Back to square one, which was the thought that a loop was probably my best bet (I had come to that conclusion a while back, but forgot why.)

Did try a shielded loop once upon a time, but didn't feel it gave me anything to look forward to. Guess I'll dig it out and try it again. Will try shielding it with copper "tape" and see what that buys me. I did try a piece of coax wound in a triple-turn loop to give me 2.5 or 3 uH with which to tune, with the shield cut away to expose the center conductor for a couple inches, but didn't feel this offered anything either. Not sure what I'll do. Poke around and try different things until I find something that works better than the rest. Any ideas? I'm all ears. I tried the whips because I had them on hand, and they were easy to install. Seems I read somewhere that contrary to conventional wisdom, the shield on a shielded loop doesn't actually shield at all, but becomes the antenna element. Anyone know anything about that line of thought? I obviously know nothing, and am trying to learn. Just don't know where to focus my energies.

Thanks,

Dave

I'm a pessimist, as you have probably concluded.

Democracy (yeah, I know, a democratic republic) exists only in fairy
tales. When it comes to money, this country's government runs roughshod
over the American people's needs every time. NAFTA, GATT and a few other
treaties prove this premise to be true. My point is hinged upon the
supposition that if there is money to be made in BPL, it will be
implemented whether it is good for us or not. Worrying about things that
we cannot change is pointless. This comes from a habitual worrier that
is trying to get a grip on it. <G>

Yes, it HAS worked before!

Now, many only wonder why it no longer works?

I ponder ALL this myself--as I have stated--and, on many occasions--I
only wonder why it ever worked???

That's been discussed on this newsgroup a number of times. You should be able to find the relevant threads via groups.google.com.

Yes, the "shield" doesn't shield the antenna -- in fact, the outside of the "shield" *is* the antenna. What it does is aid in balancing the antenna, reducing common mode pickup which can reduce the null depth. "Conventional wisdom" that holds otherwise isn't wisdom at all, but a lack of understanding of some basic electromagnetic principles.

There's undoubtedly a massive amount of information easily available on the web regarding building and using small loop antennas. All you have to do is ignore the ubiquitous "conventional wisdom" explanations of how a "shielded" loop operates.

I tend to agree with Ed. But the bright side of the situation is that, conversely, if there *isn't* money to be made in BPL, it won't be implemented. And it looks like there's a decent chance that's the case.

I don't get that number at all. Splitting the difference between 6 and 12
Mhz, say
9 Mhz, an 1/8th wavelength distance would be about 4 meters.
Anybody have a url of a page that shows receive pattern of two antennas at
different
spacings, 1/8, 1/4, 3/8, 1/2 wavelengths?
Dave, I recommend you download the demo version of EZNEC, it won't take
to long to model a couple of verticals at different spacing.

Hi Dirk,

The coax to your antenna was suffering common mode currents. These currents came from noise sources in your home (by coupling directly through conduction, or over-the-air). Those currents traveled towards the antenna along the outer surface of the coax's braided shield. When those currents got to the antenna feed point, they reversed direction and entered INTO the transmission line and went back to your receiver.

When you grounded the far end, those currents went to ground the easy way instead of through your receiver's front end.

A "magnetic" BalUn is not an effective choke. Chokes are used to decouple the transmission line from the feed point. The W2DU choke BalUn (1:1) would also reduce noise.

You were LUCKY with ground loops. When the weather changes, you may see your luck change.

I made a perfecly workable little DF once on a ferrite rod, wound with a
few turns. Worked like gangbusters on the local 2 and 6mhz stuff that I
was trying to locate.

I'll keep my fingers crossed... :-)
The soil here is partly clay/ partly sand. In winter it becomes quite
moist. Would that adversely affect the situation?

I have never seen "ground loops" mentioned in an antenna book.
Ground loops are a main problem in audio frequency equipment,
not in HF.

In high frequency equipment GROUND EVERY POINT YOU CAN
to create a quasi-reference potential area as large as possible.

The usual way to overcome stray noise from nearby sources
are:

1.) Electrostatic shielding of the antenna.
Use coax for the horizontal dipoles, and ground the coax shield
at the ends but do not create short circuited loops.
(do not confuse with "ground loops")
2. Use a noise eliminator which feeds a phase shifted signal
from a small local antenna into a combining network.
3. Improve grounding as you did.

To me it is not quite clear what happened in your case,
but antennas are and have always been much try-and-error.

>So in fact the coax shield was part of the antenna?

Hi Dirk,

Yes. And that "part" of the antenna was inside your home.

Please keep in mind that the same coax shield can support TWO currents: one on the outside and one on the inside. Even though it is the same metallic conductor, the shape creates two circuits because RF currents on the outside cannot penetrate to the inside (that is how it shields). Instead, those currents on the outside travel to a common point such as the feed and gain entrance.

Also, the reverse is true as well (when we are thinking in terms of transmission).

Put a choke somewhere along that outside circuit, and you cut off that current. In your case, you grounded it at both ends.

>The soil here is partly clay/ partly sand. In winter it becomes quite
>moist. Would that adversely affect the situation?

It has happened to me (Seattle = Rain City). The "earth" connection you use at the AC plug is NOT a shield, instead it is a safety ground. It is in close proximity to a lot of noisy circuits. Another noise solution is to move your plug to a different room's socket (on a different circuit breaker). You don't have to move the radio to experiment with this, use an extension cord. Better yet, run off battery and unplug everything but the antenna.

Remember these last suggestions if the noise returns with rain (or after a rain).

Didn't say that ALL tyranny of the majority is suppressed. And, a few years back, there was huge public outcry in Houston, TX, when a law was passed making riding a horse on the highway illegal.

"freeways" are a special case anyway.. they're a "limited access highway" (limited access means that even though your property abuts the highway, you do not have the right to put a driveway onto it)

Hi, let me clarify your problem. The most efficient radiator is one
wave length long where it is considered to be in equilibrium with a
parallel electrical cuircuit
instead of the usual series circuit. For most efficient radiation both
the capacitance and the inductance
must act as a energy storage such that when the terminals are shorted
the energy is released in a burst such that radiation can begin,
the electrical circuit by the way is often called a TANK cuircuit. In
the case of a fractional wave length radiator the pendulum type
radiation is not available for radiation and thus it travels up the
outside of the coax where it can radiate or become part of the "real
resistance" of the radiator in a similar way a vertical 1/2 wave
antenna would do when half of the applied energy is absorbed by the
ground.
Per the replies you will see what these currents are named when one
has an antenna that wants to work as a full wave length long even tho
a 1/2 wave length of the radiator is missing for max efficiency.
Hope that helps
Regards
Art KB9MZ

Let me clarify some of the remarks made. A efficient antenna is when
the wire is
one wave length long and fed at its extremities. This can be
circumvented on a loop
by winding the 1WL wire on a non conductive hoolah loop both in a
clock wise and counterclockwise
in a overlapping method (insulated magnet wire preffered)
such that the windings inductance balance to zero for a resistive
impedance
at the feed point The windings may have to be stretched some what to
balance outany stray capacitance added
or a broadcast type variable capacitor can be added if one is lazy.
The bandwidth is broad enough on most bands with a resistive impedance
of around 50 odd ohms.
If one deviates much from the desired frequencylength one will see a
resistive impedance
in the single digits so take care with the wave length measurements
This loop design based on Gaussian laws provides a broad bandwidth
with smaller physical size
compared to the standard magnetic loop design together with extra
gain. And yes one does not
need that expensive high voltage variable capacitor required for
movement around the band as required with presently known loop
designs.
By the way the element can be jumpered for use on other bands!
Have fun
Art KB9MZ
PS I have written a somewhat amaterish thesis on Gaussian antennas
for which I have applied for a patents, I am sure that a scan of past

posts on the subject will reveal the URL which I have not put in my
memory box.
Amateurs have not used this new design method as they are happy with
existing
arrays knowing that all is already known about antennas and all later
designs
must be fraudulent

Vertical Real Estate

In 2003, Clear Channel created the Vertical Real Estate division and hired Scott Quitadamo to promote its tower portfolio.

Clear Channel owns and operates approximately 1,500 broadcast transmission towers across the US. many of which are available for co-location by third parties such as cellular and PCS companies, wireless internet, fixed wireless, and other broadcasters.

Contact
SCOTT M. QUITADAMO
DIRECTOR, VERTICAL REAL ESTATE
3405 PIEDMONT ROAD NE, SUITE 500
ATLANTA, GA 30305
PHONE: 888-551-SITE (7483)

General

What does Clear Channel Vertical Real Estate do?

Clear Channel Vertical Real Estate drafts and routes Wireless Tenant lease and related documents (we are the landlord or lessor) related to the following activities:

1. Tower and Building Space Leasing to Wireless Tenants
2. Tenant Lease Amendments
3. AM & FM Diplex Agreements
4. SCA’s (English & Foreign Language)
5. Expired Lease Renewals (not term renewals)
6. Equipment Modifications and Additiona
7. Entity Name Changes
8. Unpaid Tenants
9. Shared Facilities/Infrastructure
10. Rooftop Leases
11. Other tenant leasing matters as needed.

What types of tenant leasing clients does Vertical Real Estate handle?

Anything wireless, including: Cellular, PCS, Broadcast TV & Radio, Wireless Internet, Government, Telemetry, 2-way, etc.

How do I contact Vertical Real Estate?

Clear Channel Vertical Real Estate
Attn: Scott M. Quitadamo
3405 Piedmont Rd., Suite 500
Atlanta, GA 30305
404-879-5670
towers(at)clearchannelDOTcom

Does Vertical Real Estate also handle leases where Clear Channel is a tenant on another company's tower?

No. Please contact the Clear Channel Corporate Real Estate in San Antonio.

Where can I find a Tower Site Lease application for a potential tenant?

www.towers.clearchannel.com Click the Site Application Link or contact Scott Quitadamo at 404-879-5670 (888-551-SITE toll free) for more site information.

What carriers do we have national Master Lease Agreements with?

- Verizon
- Nextel
- Sprint
- ClearWire
- Lojack

We also have commonly accepted lease template agreements with:
- MediaFLO
- Cingular
- T-Mobile
- Federal Express
- USA Mobility (fka Arch/Pagenet)
- NY State Police
- And many others

Leasing Process

What are the typical steps in the leasing process (see also Leasing Process Checklist)?

- Tenant Interest & Site Identification
- Lease Application
- Site Information (Due Diligence) & Feasibility
- Lease Drafting & Review
- Notice to Proceed & Construction

What information is required by Vertical Real Estate get the leasing process started?

- Site Identification (ASR/Coordinates/City State, Calls, etc.)
- Applicant Name, Prospect Name/Title, Contact Phone, Email, Service Type
- Application: Proposed equipment specs (lines/antennas/ground space/

power requirements).
• Timeline and Target Rent.
• Existing Lease Documents (if any)
• Purpose of lease (co-location, diplex, upgrade, renewal, etc.)

I am a prospective wireless tenant and want me to meet Clear Channel's local representative at the site, what do I do?

• Site Visits/Site Access – A site visit is strongly suggested and often requested for/by all wireless tenants to inspect the compound and discuss various engineering and construction issues related to: shelter capacity, rack space, utility services availability, backup power generation, current and proposed equipment locations, tower obstructions, and other issues.

Site access is restricted and governed by the Station Engineer or Real Estate Manager (CCO). We ask Applicants make arrangements for access at least 5 days in advance. Contact Clear Channel Vertical Real Estate for additional information at 888-551-SITE.

Do we always use the same lease template for all tenants?

• We have national Master Lease Agreements (MLAs) with several national companies. We also have commonly accepted lease template agreements with: MediaFLO Cingular T-Mobile Federal Express USA Mobility (fka Arch/Pagenet) NY State Police and many others.

• All other tenants use either the Standard Lease or a Standardized Lease Template.

• Clear Channel Outdoor Leases (Billboards) must use the Outdoor Lease Template. Existing MLA's and other lease forms are not used on Outdoor properties.

Who signs the leases and how are they distributed?

• We route all leasing documents through Atlanta and are executed by the EVP Distribution Development.

• We require 3 originals for Clear Channel plus # the tenant needs. Originals at Clear Channel are distributed to: Vertical Real Estate, Real Estate in San Antonio, the Station Business Manager, and one electronic copy of the lease is routed to the station engineer.

What is the Leasing Process Checklist?

• This is the checklist we follow for almost every lease we draft:

Leasing Checklist (Application through Lease Execution)
☐ Application Complete (all relevant info complete and correct)
Determine Lease Type:
☐ New Business *
☐ Upgrade Increase *
☐ Renewal (Expired Lease)

☐ Other
☐ Validate and Verify Site Identification: ASR and/or Coordinates and Address, City, State, and Clear Channel Station Call Letters (if any).
Pull or Create Property File Folder for the following and obtain all missing items (check shared drive and SA drive)
☐ LPD or Deed **
☐ Ground Lease (__requires LL consent?) **
☐ Structural (date_____ / Tenant_____)
☐ Tower Drawings (original construction) ***
☐ Current Tower Loading (attach Tower Equipment Detail sheet)
* Items required only if New Business or Upgrade Increase in Tower Load
**If this not available, contact station business manager and Jo Michele
*** If not available then obtain tower model number, manufacturer, and the date it was constructed from station engineer.
Send Preliminary Feasibility Checklist email, Tower Equipment Detail sheet, and copy of Application to Station Engineer with CC: to Market Manager and RVP Engineer.
(see Feasibility Checklist below)
☐ Enter Application into Payday Report
☐ Review Current Tenant Lease (if applicable) and note entity names, dates, and equipment details.
☐ Prepare chains-of-assignment if requested by Applicant.
☐ Review Ground Lease, note entity names, expiration date, and file in Property Folder.
☐ Prepare Landlord consents, if needed, and note on outside of Property File Folder if Landlord consent is required.
☐ Request chains-of-assignment if requested by Applicant.
☐ Draft (PRT) Lease and email to Scott
☐ Follow Up 5 Days after Preliminary Feasibility Checklist email to verify receipt of completed Preliminary Feasibility Checklist and Tower Equipment Detail Sheet (if not completed by day 7 request assistance via email from Station Market & Business Manager and RVPE)
Prior to Lease distribution, we must have the following in the Tenant/ Property File (as required).
☐ Structural Study or Analysis and Reinforcement Design showing the structure will carry the loads as described in the Lease Exhibit B. (if required) (attach copies)
☐ Construction Drawings or A&E Drawings or Sketch: one tower elevation and one property drawing showing the placement of the Lessee’s equipment on the site. (attach copies)
☐ Permits (Zoning, Construction, Electrical) and other governmental authorizations as required by Federal, State, County, or local codes. (attach copies)
☐ Contractor/Installer Approval by Clear Channel’s Station engineer (via email; include the name, address, phone email, and Tax ID (FEIN/ TIN) number for the company that will be performing the installation of Lessee’s equipment).

What information does Vertical Real Estate require from the station engineer? (Feasibility Checklist)
• An email is sent to the station engineer (et al) as follows;
Clear Channel has received an application (attached) from [CLIENT NAME] to lease space on the above referenced tower. Please provide, within 5 days, the following information (if checked) via email.
☐ Available Tower Space at the elevation(s) requested and if NOT, what is (are) available??
☐ Available Ground/Shelter/Building Space as requested and if NOT, what is available??
☐ Available Electric and TELCO as requested and if NOT, what is available???
☐ Ground Lease or Property Deed/Legal Property Description
☐ Name of last tenant to install equipment on the Tower
☐ Is a Structural Analysis of the Tower Required?
If a Structural Analysis of the tower is required, please EMAIL or FAX copies of the following (if checked)…
☐ Last Structural
☐ Current Tower Loading (see attached Tower Equipment Detail sheet) *
☐ Tower Construction and Load Design Drawing

I need an "Entry and Testing Agreement" to access your site, what's the process?

• Entry & Testing Agreement - Applicants requesting access to the property or the tower for any reason are required to sign an Entry and Testing Agreement. We must use the Clear Channel Vertical Real Estate form which provides customary insurance and indemnification provisions in addition to spelling out what actions Applicants can perform on the premises. You can request a copy by emailing us at towers@clearchannel.com.

Tenant Construction

Do we always require Applicants to conduct a Structural Analysis of the tower?

• Before a fully executed lease is distributed, we require all applicants to provide either a complete structural analysis by a CC approved PE, or a written waiver from the station engineer. The applicant contracts and pays for the structural.

• The station engineer is required to provide all available tower documentation. At a minimum, the station engineer must provide the tower's model and manufacturer and current loading. In addition, construction drawings, foundation design, prior structurals, etc, are immeasurably helpful.

• In the event we do not have the necessary details to have the tenant conduct a proper study, we will permit the Applicant to access and map the tower.

• All expenses related to the structural analysis are paid by the applicant.

How are proposed tenant equipment installation and construction details reviewed and approved?

• While not “required”, the Applicant is responsible for the design, production, and delivery of drawings (either professional A&E or a construction drawings sketch, at our option). Drawings must be approved by the station engineer or operations manager (CCO) prior to the distribution of a fully executed lease.

Do we allow tenants to make Permanent Improvements to the tower or the premises?

• If a tower requires substantial structural reinforcement or replacement, we may allow an Applicant to evaluate and submit a request to that effect.

• Upgrade or replacement costs and logistics are reviewed and approved by Station Management, the RVPE, and the station engineer, and if approved, are incorporated into the lease agreement.

What Steps must a prospective Tenant follow in order to be in compliance with the lease prior to commencement of construction?

I. General – Notice to Proceed (NTP Checklist)
Prior to commencement of construction, LESSEE is required to provide the following:
1. Schedule of Construction (start date and estimated completion date: specific dates).
2. Proof on Insurance as more particularly described in the Lease Section 10. (attach copy)
3. Structural Study or Analysis and Reinforcement Design showing the structure will carry the loads as described in the Lease Exhibit B. (if required) (attach copies)
4. Construction Drawings or A&E Drawings or Sketch showing at lease one tower elevation and one property drawing showing the placement of the Lessee’s equipment on the site. (attach copies)
5. Permits (Zoning, Construction, Electrical) and other governmental authorizations as required by Federal, State, County, or local codes. (attach copies)
6. Contractor/Installer Approval. The name, address, phone and Tax ID (FEIN/TIN) number for the company that will be performing the installation of Lessee’s equipment.
7. Lessee’s Construction Manager/Supervisor: name, phone and email address.
8. Lessee is required under this lease to wait for WRITTEN APPROVAL from Lessor’s engineer before commencing construction.
Commencement of construction prior to written approval or delivery of required may result is a lease default.

I do. It's my home page so I can access it with one click.

I imagine I should infer something from your question but, no, nothing. I
asked Google for "BPL" and scanned the results but still nothing came to
mind. What's up?

So the safety ground is a bad RF ground in most situations.

Thanks again for the clarification Richard!

From a safety viewpoint all ground points are equal.
For _RF_ however, one ground point _may_ be better then another,
depending on how the wiring goes through the house, and where the
ground wire is picking up QRM, hence Richard's suggestion to feed the
receiver from a wall outlet in another room.

Perhaps that is what they really mean, that the gain is certified for ERP
calculations.

Note (for one example of many) that in an antenna system consisting of a 1/2-wave, center-fed dipole driven by a matched, balanced transmission line, the dipole itself radiates virtually all of the r-f energy present at the antenna feedpoint.

The radiation efficiency of a system as in the above example, but using a full wave dipole is no better than the 1/2-wave version, other things equal. The full wave version just has a different radiation pattern.

==========
Even better: If no AC is required but say 12 -14 V-DC , run the receiver
from a sealed lead-acid battery and only have a RF earth.

My complete station runs on 12V batteries (charged by 2 solar panels and
a wind gen) ,resulting in NO mains born interference .

If charging from mains ,one could switch-off charging while receiving
and only put charger on battery or batteries while transmitting.
however when the batteries are on the charger all the time the batteries
will probably 'absorb' any mains noise ; moreover the mains power supply
unit then does not need to supply peak current to the transmitter ,just
the average current which for a typical 100 W PEP transmitter (even with
compression) is not more than approx. 8 Amperes.
In such a situation the station will also always be available (for some
time) during a power outage ......emergency comms.

With batteries the supply voltage will on average be below 13.8 V ,hence
the transmitter output will be slightly lower resulting in a signal
which will be lower but never more than a small fraction of 1 S-point.

Note : When reducing power by a factor 2 the resulting signal will be
reduced by half 1 S-point.

BILL
The best way of using coax with antennas is by stripping the PVC and
soaking the braid
in polyurothane so the clock wise windings are insulated from the
counter wound windings
By shorting one end of the braiding you can feed the other end i.e.
the two different windings
2where the actual span is somewhat less than a 1/2 wave (calculate
the true wire length)
The same can be accomplished by using somewhat less than a full wave
length folded back on itself
and directly feed the ends. This arrangement takes the fragility away
from the span by not feeding at the center
as well as using the center wire of the coax for mechanical strength.
This method comes in quite usefull when the need is for a 160 meter
antenna where you can wind the coax cross wise fashion so the ends for
feeding finish together.
This comes out at around 60 turns on a 2 foot former. This method
gives more gain over 1/2 wave designs in a similar way that a quad or
loop of one wavelength exceeds others. You can also use a single wire
instead of coax for cheapness if you wish but ofcourse you like coax
but this way you can join scraps of coax and solder them together
without bothering with individual strands. This method by the way does
not require a ground plane so you may leave the barrel on the ground
or place it on top of the tower for rotation purposes. You can have a
lot of fun with this antenna if you can also rotate the axis of the
barrel by useing two rotators or a combination satelite version.
Note thatusing a full wave length antenna you achieve tha same
gains(~ 3db) that a quad obtains over the standard fractional WL

length radiator(~2db when using single wire). Feed impedance is around 50/60 ohms resistive and is quite broad banded. The above is based around Gausswian formulae that also conforms with Maxwellian laws so you can use suitable modeling programs such as AO to derive all specifications. The above is subject to possible U.S. patents acceptance at this time
Enjoy

1562. Ringo ARX-2 vs ARX-2B - What's the deal?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-22 15:28:32 UTC
From: Kevin Hastings <myfamilydotcom@hotmail.com>
Message-ID: <46f534a8$0$4038$9a566e8b@news.aliant.net>
Source record: 36192

I bought one of these at a hamfest from a SK's estate and thought it was a ARX-2 and then noticed the 52" coax harness attached to it and realized that it was probably a ARX-2B which seems to be the same except for the 3 radials which I guess didn't get sent to the hamfest.

Reviews of these 2 antennas seem to almost use the 2 model numbers interchangeably so the question is... Is it worth making up a radial system and taking another 5 feet of mast to re-manufacture this thing into a ARX-2B?

What would be the advantage? Maybe somebody's used both.

Thanks,- I was sure somebody out there knew this

> Roy Lewallen, W7EL

If it was just for receiving I would make two antennas in coil fashion
as shown every where
on the net, connect them together with a half wave length coax and try
stretch them apart as much as room suplies and then roll the excess
phasing coax up. The cb's have the super scanner antenna that partialy
follows this principle using 1 wave length antennas with the
connecting coax folded and pushed inside the connecting aluminum
channel. Using a rolled antenna tesla style with them being physically
close together would be an interesting experiment. Look up in the net
home made radios for the station tuning method and also you might want
to choose different methods to connect them starting with a wire
connecting the two wound antennas at the top and feeding th bottom!
(that method by the way requires the two antennas to be wound
inopposite directions) I imagine you could get a null just like
turning an inside tv antenna because these stations in this
frequencyare high power as can be seen when a rogue station opens up
ontop of the station that you are listenning to and want to null out
of the picture.
Have fun

I have used the ARX2B with and without the decoupling stubs and didn't
notice any real difference. Theoretically, the decoupling stubs flatten the
radiation doughnut which provides better signal toward the horizon. I guess
I didn't operate many stations that were out there far enough to notice any
improvement in range. How high the antenna is mounted also plays into the
range. Mounting it low would probably remove any advantage provided by the
coax and decoupling stubs.

My understanding is that the original Ringo design doesn't do a good job of decoupling the feedline (and mast, if conductive) from the antenna. There can be a significant amount of RF current flow on the outside of the feedline, below the impedance-matching loop/ring. This radiates RF which combines with that of the radiating section, altering the antenna's pattern to some extent (I think I've heard people say that it can cause the antenna to "squint", with its main radiation lobe pointing above or below the horizon). Because feedline RF depends on the length of the feedline and its grounding configuration, feedline-RF issue makes the original Ringo somewhat sensitive to the specific conditions under which it's installed - works great for some people, poorly for others.

Ordinary copper-pipe J-poles can suffer from the same problem, but as they're a lower-gain antenna with an inherently-broader vertical pattern I suspect that the problem is less noticeable.

The coax harness and radials (which you can probably replace with quarter-wave sections of aluminum rod-stock, suitably threaded) act as a decoupling section, isolating the feedline from the antenna and making it less sensitive to the conditions of installation.

You might be able to achieve a similar effect by simply rolling up a couple of feed of the top of the feedline into a coil 4-5" in diameter, just below the feedpoint, and insulating the antenna from the mast itself.

Hi Frank,

You are a proponent of one of my suggestions; yes, battery operation
(as I have as well) solves many issues.

>My complete station runs on 12V batteries (charged by 2 solar panels and
>a wind gen) ,resulting in NO mains born interference .
>however when the batteries are on the charger all the time the batteries
>will probably 'absorb' any mains noise ;

This is true only if the interfering voltage appears across the
battery - a rare occurrence unless you are mobile and speaking of
generator/alternator whine.

If batteries are float charged, then there is a path from the radio,
through the batteries, to the charger, to the mains and common mode
follows that path. Similar common mode paths of (in)convenience take
time to discover - like an external DSP powered by a wall-wart.

I don't know what your credentials are for you to make such a
statement but it is a free world after all!
A quad radiator is a wave length radiator with a gain more than a half
wave as one sample.
Computor programing confirmes more radiation from full wave antennas
and mathematics according to Maxwell,s rules substantiate it. I can
understand not believing computor programs but I am very interested in
any mathematical data that would support your stand which is contrary
to the mathematics that I and others support.
What you are stating is that an attena in a series cuircit format
produces the same radiation as a parallel or tank cuircuit. I am more
than eager to read the contrary mathematical proof that is contrary to
the mathematics that I hold true. You may have hit on the true
explaqnation of radiation which Einstein, Planck and many others went
to their grave without solving it

I run all my HF gear off of a battery bank...

1- it is cheaper than a power supply in most cases.
2- it works when the power (grid) is down.
3- lower noise problems
4-instant power on demand..ie no real power curve when you key up (most battery(s) (I like yellow top optimas) can pump out several hundred amps for a short time if needed.
http://www.1st-optima-batteries.com/deep_cycle_battery.asp
If you really think about it, there are many reasons to run off of a battery bank. Including emergency communications...and if the battery(s) voltage drops in extended use...there is always a set of jumper cables and a vehicle to charge it up again...

In your first post you wrote, "The most efficient radiator is one wave length long where it is considered to be in equilibrium with a parallel electrical cuircuit," and that is what I responded to.

Now you are writing about gain. Efficiency and gain are not synonymous.

Both of the dipole antennas in my previous post will radiate nearly 100% of the r-f energy available from a matched, balanced source connected to their input terminals. Therefore the radiation efficiency of those two configurations does not favor the 1-wave over the 1/2-wave, which was your opening premise.

They won't have the same gains in every direction, because their radiation patterns are different. Same for your quad and "half wave" example.

RF

Absolutely.
>
> What would be the advantage? Maybe somebody's used both.

Yep, I had a ARX-2 which I converted to a 2B. I did tests to see
the difference. It was large.
What the deal is... That extra section is mainly a decoupling device.
This decouples the antenna from the feedline, which can skew the
pattern upwards off the horizon. Gain is useless if it's pointing
towards Jupiter...
You don't need any more mast per say. The radial set clamps
to the existing mast you are using now. The 50 inch coax
section connects from the feedpoint to that radial set.
I made all the parts to convert mine myself but I imagine you
can order them from cushcraft.

I have written a simple explanation on the operation of the so called
'shielded loop' at http://www.vk1od.net/shieldedloop/index.htm .

You may find the article of interest.

If you read and understand the content of the article, you will see the
pitfalls in using tape to 'shield' a loop.

O.K. I may have muddied things. I hold to the fact that a one
wavelength dipole will always radiate at a higher efficiency than a
1/2 wave dipole. The example I gave as for an instance was a quad
versus a 1/2 wave dipole.
This is readily seen by any operator empirically. Mathematically it is
proven that way also even tho both are in accordance to Maxwell's
laws. You could I suppose compare a series antenna with a parallel
circuit i.e. a tank circuit that could reinforce your point and that
is what I hoped you would come up with to bolster your point without
resorting to a computor program based on Maxwellian laws. There is
much discussion about what creates radiation and I thought you may
have come up with something that we can all learn from. Eventually
even tho the past masters have died some one, possibly you, will
discover that which has eluded all, even quallified scientists with
huge resumes. I am willing to give you a hearing which does not often
happen on this newsgroupAs an aside I suspect that a single quad
element will beat a dipole anyway regardles of what the fields
differences that you point to but again I am very interested in any
mathematics that defends your possition possibly starting witha
parallel versus a series arrangement since it is very clear whatstarts
radiation in the parallelcase but unknown mathematically for the

series circuit.
Very best regards
Art Unwin....KB9MZ

Wait a minuit! you stated that a half wave antenna was nearly 100%
efficient and therein may be the true answer
A quad is often considered as two dipoles even tho there is only one
feed point thus efficiency per unit!Then one can refer to efficiency
per unit length. Is that your point?

I was given an Arx2 on Guam. Looked as if it had gone through
numerous typhoons, and was missing the hairpin match. Not having a
manual or anything (and pre-internet), I fiddled with a piece of
copper wire until I got tired of it. So I gave it to a fellow ham,
who unscrewed the top section and threw it away. It matched just fine
with only the ring at the bottom.

Power in vs power out of a system. I know how to do this for a
parallel circuit ala
a tank circuit where energy is released in equilibrium fashion. For a
half wave dipole
you can't have two energy containers so you may or may not be heading
for excess end effects because of high voltage looking for where it
has to go. (Personally I don't know how a half wave radiates because
that form vuews the cyclic current continually radiating as the time
variant which is contrary to all other radiations i.e. a spark plug,
ahydregen bomb which is a bigger container that a flyback transformer
and a bigger container will always beat a small container with respect
to out going accelleration of energy, particles or plasma which ever
you may prefer)without any known proof.I believe that is why the quad
was designed to get away from the spark plug type emmissions at the
ends of the radiator.
On the other side of the coin, since both a quad and a 1/2 wave dipole
is assumed to be suitable drivers for a yagi array both must be bi
directional so gain is applicable when comparing these radiators I
would would think!
Best regards
Art

Richard , I have been reviewing antenna fundamentals as per the
engineering
handbook by Jasik second edition where it states
"The method of computing radiation patterns foir thin linear radiators
is basic regardless of length or complexity of shape " if one assumes
that the current from point to point is sinosoidal. This statment is
consistent with the present assumption that the time variant current
is sinosoidal at every point along the length of the antenna.

Well I have clearly shown for a parallel circuit you cannot pursue this assumption anymore even tho the books state otherwise. The books are not incorrect if the mathematics produced by such a assumption is correct which mathematicians often do when there is an absence of knoweledge to the contrary. What I am declaring is the tank circuit ala parallel circuit which demands a full wave length antenna is the most efficient because the assumption by mathematicians is incorrect. Following Gauss's laws for static and enlarging the format to a dinamic situation i.e. time varient then the demand is for a arrangement in "equilibrium" which cannot be attained with anything other that a full wave length. Following this logic mathematically it concurrs with Maxwells laws and any computor program will move away from any half wave radiator if you ask for maximum gain and allow it to computeaway from a planar arrangement under Maxwells laws.(By the way I always refer to a full wavelength radiator which by no means infers
a center feed. In my case I usually follow the end fed aproach because of a dual windings but in opposite directions)
If Maxwell had in his portfolio an expanded Gaussuian law for making his jigsaw complete the overall picture would have been completed in no time. Unfortunately he did not have this at hand but instead used Faraday and others input
to arrive at the correct answer but with gaps in the info provided. It is for that reason I persued this analogy which is new and contrary with existing assumptions even tho the eventual answers are the same. BUT the analogy of assumption of time varient current of itself produces radiation is incorrect at least for a parallel circuit, aspark plug with a flyback transformer or even the emmisions of a nuclear explosion. I don't think there is a need to dither on the subject anymore since nobody knows how a fractional wavelength antenna really works whereas I am promoting a view of an arrangement in equilibrium and the commonly used approach by Gauss and others with respect to a closed arbitary field. Enjoyed the discussion tho, very thought provoking.

> versus a 1/2 wave dipole.
> This is readily seen by any operator empirically.

I've never seen it here. For that reason, I hardly use loops.
Neither vertically oriented, or horizontal as for NVIS use.
I don't see them as worth the extra trouble. Being I tested
them on 75m using NVIS paths, a noticable difference in
efficiency should have been readily apparent. It wasn't.
In fact, I usually has slightly better performance using the
dipoles, which I think was due to the bulk of the max current
portions of the antenna being higher above ground in general.
The loop sagged a bit in areas, and wasn't all that high above
ground. The more wire near the ground, the more ground loss
in general.

>Mathematically it is
> proven that way also even tho both are in accordance to Maxwell's

Where is the math? You should find a very slight difference
at best..
It's common knowledge that even a short piece of wire 1/10
of a wave long will radiate nearly all the power that is applied
to it.
You can go lots shorter than that if you want.
If even a short piece of wire will radiate nearly all the power
applied to it, what is the point on harping about some magical
properties of a full wave length of wire?
Art, you are starting to bark at the moon I'm afraid...

I was going to comment on some of your other posts, but I
think I'll spare you the increase in blood pressure.
All I can say is that you are starting to wander off in
mumbo jumbo land again..
Replacing known science with conjured mumbo jumbo is no
way to live.

Got it. TKS

However, I'm afraid the effect of hams boycotting Google would be
negligible. Our strength lies in our ability to lobby the governement.
Does this carry enough weight, compared to the dollar-power influence of a
big company? I don't know. I'd like to think there are still government
officials who are uncorrupted.

Art, I'm curious concerning what kind of mind-enhancing substance you were on when you wrote the above post.
As far as I can tell, this post concerns the coaxial dipole. However, I don't discern any relationship between
your post and the coaxial dipole.

What does "60 turns on a 2 foot former" have to do with the coaxial dipole?

And what is the "barrell" that you can leave on the ground or put on the top of the tower for rotation
purposes? Rotation of an 80-meter dipole with a barrell on the top of the tower? Art, you have been smoking
too much liquid polyurethane in your Gaussian pipe.

Every Self-Appointed-Guru who got his "Certificate of Guru-ism" from a Cracker Jack box has forecast it is doomed to failure, can't provide the necessary bandwidth, would be easy to "jam", "just won't work, etc., etc.

Let's hope somewhere along the line their claims of doom and gloom bear some small element of truth--so much credibility has been lost by so many, would be a real shame to see 'em lose more (if that is possible!)

This "credibility gap" has seemingly swallowed many whole ...

Art, it distresses me to read the misleading statements you profess to be true in your posts.

There is no difference in the 'efficiencies' between a full-wave and a half-wave dipole. Let's assume the wire
size and conductivity of each dipole is such that we can say they both radiate 98 percent of the power
delivered to them. Let's also say that the same amount of power is delivered to both dipoles. What now is the
difference in the radiation between the two dipoles?

The only difference is in the SHAPE of the radiation patterns--the full-wave dipole will have a somewhat
narrower lobe in the direction broadside to the dipole than that of the half-wave dipole, therefore deriving
slightly more gain IN THAT DIRECTION than that of the half-wave, but with less gain than the half-wave in all
other directions. Consequently, the total integrated power in either radiation pattern will be exactly the
same!!!

If you want to express the mathematics of the conditions I described here according to J.C.Maxwell's
equations, you will find that Maxwell's equations fit the conditions EXACTLY.

Source record: 36220

If you'll look back at some of Art's postings, you'll see that he consistently uses the word "efficiency" in a way that's contrary to the universally accepted definition. His meaning of the word is more like gain, but sometimes including communication effectiveness in some way. In fishing through earlier postings, you'll also see that I implored him many times to either use such words as they're universally understood, or else explicitly define what he means by them. The reason for the requests was to help him communicate what he was trying to say, rather than leave a trail of misunderstanding and confusion. All my requests did, however, was make him intensely angry with me, and no definitions were given or change in usage made. I hope this recent round of requests for clarification will have more effect than I was ever able to accomplish.

Apparently there is a big difference from istallation to installation
without the decoupling mod the 2B provides. Ive heard many varied reports on
how well the -2 performs and what you should do to make it perform well.
Some say metal mast, others insulated mast. Some say install it at X height
others at Y, use a choke in the coax, other say thats the worst thing you
can do. Some praise the antenna others curse it. You should get the idea by
now.

For those who went to the 2B some say its better some say its worse thn the -2, go figure.

Jimmie

Of all of the 2 meter non mobile verticals I have used over the last couple of decades, the ARX2B is my favorite, in spite of my previous comments.

Walt. I have no problem with Maxwells laws but I do have a problem
with a mathematical stunt to measure radiation
of a half wave dipole based on one having to accept that at all points
on the radiator the current is sinosoidal.
There is no distinct analysis with the specifics of radiation. period.
Using a parallel circuity ala tank circuit
insights are produced that radiation is created by the shorted energy
containers of capacitance and inductance which is an intrinsic part of
any radiator in distributed form. The tank circuit is well documented.
So the question now becomes, at least for full understanding of
radiation is how does a half wave radiator follow the format shown by
a
spark plug with a flyback transformer or a full wave radiator or even
the blast from a nuclear bomb?
Yes, a half wave antenna also has distributed inductance and
capacitance energy containers but how is the mechanism
shown by the tank circuit implimented when the arrangement is not in
equilibrium?
Now I think I know what happens but I am interested in contrary
thoughts from those skilled in the arts without the
retoric. As an aside, why does computor programs drift away from
planar form radiators as well to full wave radiators
when the computor is asked to compute for maximum gain? Is this like
the quadratic equation with four answers where you get to determine
the imaginary answers? I would suggest for starters those that are
skilled in the art quantify the energy used for end effect radiation
either in the normal atmosphere or in the rarified atmosphere of Quito
Equador when Tesla type emmissions are visable? Without assumptions
ofcourse!!!!

What if the 1/2 wave dipole was made of super-conducting
material, i.e. zero loss except for radiation?

I dont know his credentials either but Richard is absolutly correct.
Efficency is the ability to radiate the signal and not turn it into
infra-red energy and has nothing to do with gain.

The Math:
Efficiency = (power applied to the antenna system - power turned into heat
by the antenna system)/power applied to the antenna system.

Doesnt take a computer, doesnt take Maxwell or Einstien to explain. 5th
grade math works pretty well in this case.

The best thing the OP can do for his existing antenna is install a good
ground system and impedance matching networks, antenna tuner. If I were
really serious about it I would invest in an antenna analyzer so I would
know when my antenna is tuned for optimum match to my radio and log the
settings of my tuner. With the ground system and antenna type he has I am
sure the ground resistance is soaking up most of his signal. He would surely
benifit from improving his ground system.

In comparing two antennas with similar omni direction radiation field
I state that gain in the field is indicative of increased radiadion
but that is a side issue brought up as often is in this newsgroup in
tha absence of a point by point debate. That method of responding is
pretty much used by all polititions. If you state what you THINK makes
the "best antenna" from accurate empirical data then I have no problem
with what you say, I just don't agree with it.
I say that because you focussed on drive or feed impedance when it is
well known that a matching impedand does not infer we have a matching
impedance in the system. Am illustration of the point. The new touted
antenna from Rohd
island university proclames a shortened antenna with a 52 ohm matching
impedance. Since a half wave antenna is not in equilibrium the energy
for themissing half must go somewhere. In the case of the new antenbna
the extra energy went back into the feed line and possibly could have
radiated from there and not the antenna. The ground plane that you put

forward infers that the ground plane is the other half of a equivalent full wave dipole, and it may well be if one can say that the ground plane radiates and prevents the ground wasting the energy. Personally I don't believe that ground radials radiate but that is O.K. So how is this new fangled antenna corrected to radiating efficiently.
How is that done? The antenna uses an inductive turnsfor shortening a antena thatis not in equilibrium so to bring it into equilibrium you add a mirror immage of the antenna including the windings and connect the two at the top together with the image antenna wound over the initial antenna such that the extra indunct becomes balanced(not cancelled) and thus one can feed it at the two wire extremities. Now you have no end effects energy losses and the circulating current has no need to find a way to balance the circuit by seeking the ground or backtracking up the feed line.It takes no time at all to prove this with a small home made antenna and it is that what I was sugesting from the beginning. By the way this is exactly what the scientific community has been pursuing with the anttena
therom of merging electrical and magnetic field as well as others. Until now nobody was aware that if Gauss had continued with his static theorem and enlargened it to a dinamic basis more information about radiation would be revealed with consequenct advances as to what creats or starts radiation rather than continueing with a situation founded on a assumption of which there is no proof. The theorem of an extended gaussian logical strategy to bring it into the format of radiation production destroys the present assumptions alluded to both in mathematical term and also in empirical terms without deviation from Maxwells laws with the extra proof that computor programs built around
Maxwells laws also confirms the equilibrium position. Now I have no problem with people that all existing designs are better but for sure industry and the younger generation is not opposed in reviewing perceived improvements since they are not addicted to preventing change. The bottom line is that a person asked for info and it is upto him to choose which he will accept and one should not get into distress if counter information becomes chosen.
Have a great day
Regards
Art KB9MZ

>consistently uses the word "efficiency"

Oh, this thread had me a bit confused. I didn't see where you guys suddenly started taking about efficiency, where did that come from?
Now Roy clears things up for me, it was due to a posting by "Art." See, Art is in my killfile, and my good old newsreader effectively clobbered his post. Art has been in my killfile for months now, permanently, because it always seemed whenever he posted something it resulted in a rash of waste-of-my time replies, of folks trying to straighten him out, and I don't think anyone ever has. So now that this thread has deteriorated..... "Aerial grounding" goes in my killfile. CUL.

So that I don't get flamed too much, I will start a posting on a little project I am working on here, which is incomplete. I am titling it "Beverage antenna, feedline pickup."

1600. Beverage Antenna, Noise pickup

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-23 16:41:08 UTC
From: ricknj10@hotmail.com
Message-ID: <46f69291.1162984@news.optonline.net>
Source record: 36230

I was reading in ON4UNs book, a section about Beverage antennas and decided to do some checking on mine, which is celebrating its ten year anniversary this month.
Mine is 575 feet long, 6 feet high, with sloping ends, oriented NE. Termination is 500 ohms into a ground rod. Feedpoint also has a single ground rod to which is attached a potted matching transformer I got at a hamfest and supposedly designed for this purpose. Feedline is 150 ft of RG8X which is not grounded at the antenna but just lays on the ground in the woods. Now, this is my first and only Beverage and there are times when I am literally amazed at what it can do. It pulled the 3B7 out of the noise and made him armchair copy on 80 meters when he was simply not there through the noise on the 80 m dipole. Now I see why some times there were no stations calling him, and how I was able to get through. I play with it on the BC band to test if it is really directional. I use my 80 meter dipole as a reference. For example during the day, here in NJ WBZ in Boston is nearly inaudible on the dipole but Q5 on the Beverage. The opposite is true for KDKA in Pittsburgh, so I know it is directional, just don't know if it could work better.

In the book they talk about how it is best if the transformer has an isolated winding for the 50 ohm input, rather than a bifilar wound one in which there is dc continuity between all windings. I checked mine and it does have such continuity. So I may be replacing it with a homebrew one shortly, maybe after I get some comments from users of this newsgroup.

Also the article warned of the effect of common mode currents on the shield of the coax degrading the pattern of the antenna so I did a test to see if mine was infected. It involves simply disconnecting the feedline and shorting the end, then checking to see if there are signals to be heard. On mine I did not hear any signals on any ham band, so went to the BC band where I heard a couple signals. One is a broadcaster about ten miles from here. It was audible although the S meter didn't budge. Switched to an 80 meter dipole and it was 20 over 9. So it appears to me that my feedline is quite good, and not picking up much common mode currents, but that is as far as I have gone. I haven't installed any choke nor grounded the feedline out in the vicinity of the Beverage yet. Any opinion, if I would see any difference by putting ina common mode choke there or replacing the transformer?

I just read the following on one of the mailing lists I subscribe to:

"Quarter wave ground mounted radials are a waste of wire and a hold over from the olden days. Check the antenna handbook, the new philosophy is more and shorter. The thing is that the bulk of the energy from the vertical antenna is near the base of the antenna and this is what you are trying to capture. A quarter wave radial sounds logical but the planet will detune it so a quarter wave means nothing to the current."

What say you all?

Equation (1-1)

efficiency = power radiated by antenna / power accepted by antenna

There is absolutely nothing stated here about "Gain" because radiation
is in every direction. An antenna is a passive device, it cannot
exhibit gain. Johnson and Jasik sez: "if one has a lossless antenna,
the directivity and gain are identical."

Equation (1-2): "The total power radiated from the antenna is" the
measurement of radiation intensity in watts/sr in every direction from
an antenna.

Equation (1-4): "Directivity is the measure of the ability of an
antenna to concentrate radiated power in a particular direction."
which is a sub-portion of the total radiation.

We can measure the total power of all radiation (EZNEC provides this);
we can measure the power accepted by an antenna (EZNEC provides this);
we can measure the power in a particular direction (EZNEC provides
this).

>"The method of computing radiation patterns foir thin linear radiators
>is basic regardless of length or complexity of shape "

There is for EVERY length.

>"if one assumes
>that the current from point to point is sinosoidal.

"for the case of a thin half-wave radiator which can be assumed to
have a sinusoidal current distribution"

This statement is NOT about efficiency and it specifically recites
what can be said about:
1. radiation patterns;
2. radiation resistance;
3. "gain" (directivity);
4. input Z.

We, in this group, quite typically express ALL of these qualities for
ANY antenna on the basis of SPECIFIC physical dimensions and

frequency. When we do, there is barely a half dB variation in any answer, and often better when all SPECIFIC physical dimensions and frequency are provided by the claim maker.

As you often fail to provide this SPECIFIC information, then your claims descend into the category of myth and superstition (you can call it hope and desire).

>What I am declaring is the tank circuit
>ala parallel circuit which demands a full wave length antenna is the
>most efficient because the assumption by mathematicians is incorrect.

This is superstition.

This Voodoo can be easily tested. The first part of equation (1-1) from the authors you quote demand you supply the SPECIFIC power accepted by an antenna. You also fail to supply the second part of equation (1-1) that states the SPECIFIC power radiated by the antenna.

Voodoo = 100%

So, to SPECIFIC counter proofs:

A half wave antenna in free space:
length = 33.43 feet
wire diameter = #12 wire
frequency = 14.28127 MHz
input Z = 72.12 ï¿½j0.00 Ohms
Power accepted by antenna = 100W
Power radiated by antenna = 100W
Efficiency = 100%

Absolutely same antenna in free space at its full wavelength frequency:
length = 33.43 feet
wire diameter = #12 wire
frequency = 28.463975 MHz
input Z = 4257 ï¿½j0.00 Ohms
Power accepted by antenna = 100W
Power radiated by antenna = 100W
Efficiency = 100%

BOTH antennas exhibit radiation patterns IDENTICAL to Johnson and Jasik. BOTH antennas exhibit input Zs IDENTICAL to Johnson and Jasik. BOTH antennas exhibit radiation patterns IDENTICAL to Johnson and Jasik. BOTH antennas exhibit radiation resistances IDENTICAL to Johnson and Jasik. BOTH antennas exhibit radiation gain (directivity) IDENTICAL to Johnson and Jasik.

When either of these two are off-center fed the efficiency DOES NOT CHANGE:
Power accepted by antenna = 100W
Power radiated by antenna = 100W

Efficiency = 100%

>nobody knows how a fractional wavelength antenna
>really works

Total ignorance reveals:
Voodoo = 100%

Equation (1-1) and (1-2) are for any size antenna. All of this stuff
is in the FIRST TWO PAGES OF THE BOOK.

On the very first page of "Fundamentals of Antennas"
"If the current distribution on a wire is known ...
then the radiation pattern and the radiated power
can be computed."

Marconi could measure current distribution 100 years ago.

The authors, of course, give treatments for antennas of all sizes,
otherwise the book would only be three pages long.

Arthur, stop coloring the pages with your crayons long enough to try
reading at least these three pages. :-0

Message-ID: <1190568794.245105.44250@y42g2000hsy.googlegroups.com>
Source record: 36234

For full understanding of how Maxwells laws were generated one has to
check if eny proviso's were written in.
Ffor instance I suspect that there was a proviso for equilibrium in
every law thar Maxwell used for his summation ofr laws there was an
exceptance by all the masters that without equilibrium the who univere
would fall apart.
Some where along the line somebody deviated from this proviso and made
the assumption that at every point on a radiator can be seen as a sino
soidal current that causes radiation because the assumption was needed
to conform with Maxwells laws while ignoring the dictae of the masters
that the laws of the universe is bound by
by equilibrium so the assumption was conncocted to "solve" the 1/2
wave problem. Can anybody versed in the art point to one of the many
laws at his time were not based on equilibrium. In other words did any
of the work he used specifically addres things that were NOT in
equilibrium to justify its use for items not in equilibrium to
substantiate the use of Maxwells laws to derive its function. Being a
mechanical engineer I am not well informed
of all the doings of the masters

>common mode choke there or replacing the transformer?

Hi Rick,

None whatever. Your tests proved your coax was being effectively choked by the proximity of earth. However, this may change with weather and you should repeat your tests throughout the year as the seasons shift. Further, you may gain from the historical data I provide below.

Another test: simply listen to the coax shield (move its connection to the antenna input and leave the center conductor open). Make sure to provide a good ground for your rig (in fact, you should NEVER ground your rig through a coax if your rig has any other path to ground). If your coax is grounded at the antenna site, you should isolate this connection (absolutely nothing connected at the far end).

Sorry for the parentheticals, but ALL grounds should be connected TOGETHER independently of your feedline. This may mean another 725 feet of wire (not always observed, but it is code). However, having said this, it does not follow that you will actually observe any improvement. It could also kill the Beverage action (due to the field being retarded by the earth which gives rise to a sloping, traveling wave).

As no one is probably very well instructed on Beverages (which may include ON4UN because his readers never cite any actual historical data), you may well do to go to the source:
Harold H. Beverage & Anti-static tuned antennas with Chester W. Rice.
''The Barrage Receiver
Using a 10 mile long wire on the ground, they eliminated static originating in the Caribbean that masked European signals. The wire described ran in the opposite direction of their antenna pointing (just as yours) into central Europe.

These tests were performed nearby you (albeit 80 years ago) by RCA. If you live in proximity to a good engineering library, I can supply many inventors' names you would do well to research.

The ground does detune ground
mounted radials because the fields are attenuated by the
ground. Twice as many 1/8WL buried radials may work as well
or better than half as many 1/4WL buried radials.

Hi Rick,

Sounds like the ghost of Reggie.

So, in honor to his aphorisms and homilies, it should be noted that
adding more wire to that which is conducting nearly nothing - is a
waste of wire.

If we are to reduce this to sound-bites, then the taller the radiator,
the longer the radial(s). If I recall Reggie's other homilies
correctly, there should be a one-to-one correlation (length=height).
As far as efficiency goes, the difference between 20 radials and 120
is hardly noticeable on the S-Meter. Real engineers can measure
differences, but they are far and few between (and don't QSO).

back again art?? still stuck on 'equilibrium'??? 'equilibrium' is a nice catch word. and yes, many 'masters' heartily believed that everything had to be in 'equilibrium' with something or another. but we have come a long way since then. there can be no energy flow between things in equilibrium, and we all know there is energy flowing in antenna elements. if there wasn't they wouldn't radiate. and we can directly measure it with current and voltage probes. so while maybe the static case of coulomb's law may be said to represent 'equilibrium', none of the others needs that... in fact none of the others would exist if everything was in 'equilibrium'. the current, curl, and d/dt parts of the equations are all a representation of non-equilibrium conditions that must exist for those equations to be of any use. so get out of the 19th century and into the 21st and join the rest of us in the understanding of the dynamic world around us!

...yes, but radiation only in limited az/el sectors, at the expense of loss of radiation in the other sectors.

The field gain in a particular direction is due to the change in pattern shape, not an increased radiation efficiency of the "better" antenna.

For the same input power accepted by different antennas, the total power radiated into the volume of space is the same, no matter what the shapes of their respective radiation envelopes.

don't claim that until you have modeled it in full. it may actually have
lower currents spread out over the longer wire thus giving smaller I^2*R

losses. consider this 'obvious' case... 1V across 100' of wire that measures 1ohm... draws 1A... power dissipation is 1^2*1 for 1watt.... now i double the length of the wire expecting to get more heat... now there is 1V across 200' of wire, but the resistance is now 2ohms... I is now .5A, .5^2*2 = .5watts. those squared terms will get you every time.

1616. Speedup NEC-Engine, using multiple CPU-Cores

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-23 19:34:37 UTC
From: oeguet@gmx.de
Message-ID: <1190576077.731409.75750@n39g2000hsh.googlegroups.com>
Source record: 36146

Has anybody a solution to speedup the NEC-Engine, using multiple CPU-Cores?
In standard use, only one NEC-Engine is running. The NEC-Engine does not use multi-threading technique and therefore only one CPU-Core is running.

Todays computers have multiple cores. Even I am using one with two cores (Intel Dual-Core). And there are more cores available in the future (3,4 and more).

My question is, is threre a solution for speeding up the antenna calculation using NEC2/4-Engine? If not, I plan to code a wrapper NEC-Engine, that is able to busy all CPU-Cores and merging the results to one output file. Especially antenna calculation can be easly divided into multiple parts (eg. radiation pattern division). If there is a solution, I do not want to reinvent the tire again.

Regards,
Aziz

> - Show quoted text -

Well David my checks on books on the subject that revealed that all Maxwells laws
conform to standard boundary conditions. When I started enlarging the static law of statics I was cogniscent of the fact that the same boundary conditions must exist to maintain plausability. This forced me to make sure that the additions within the boundary must not alter the boundary aproach. I could not uset 1/2 wave antennas be3cause that violates the laws laid down by Maxwell in all his laws so I used full wave radiators to continue, after all it xcannot be a law if you have to make asumptions. I applied a time varying field to make it dynamic so that it conforms to Maxwell
laws Thus in effect my aproach should be considerfed law
Now we come back to existing aproaches of present day scientists and they have chosen to ignore the required conditions and in its place started to apply assumption which you are not allowed to do with laws only theories. Scientists and others further violated existing laws ala Maxwells laws which are based upon equiulibrium in all cases and used it where it is not applicable.
Now all computor programs are based around Maxwells LAWS so how come it is used in violation of those same laws?
I followed the boundary laws in my expansion of Gaussian law where the results conform to Maxwell and as I have described earlier the tank cuicuit is the result but without having to make assumptions assumptions because I abided by LAW. At the same time it clearly prooves that asuumptions made by scientists and programmers are clearly in error of itself. Since I like to do things from first principles it was my responserbilty to ask electrical people and those familiar with the state of the art that the principles I used were "not out of date" ie now revised. One response came from a ham with a Doctorate working for MIT. He clearly stated that mathematics support my approach and showed how they were in conformance with Maxwells LAWS. Nobody concurred with his finding and none supplied reasons why except that 'you can't do that'! So until somebody of stature challenges his confirmation I stand my ground. Now W7el is making a living from programs that are applying Maxwells LAWS to items within a boundary that are NOT in equilibrium which is INCORRECT. Others by the way deny the existance
of boundary Laws ala equilibrium as if it does not mean anything.
Ofcourse programmers say I only copied what the government released ala if it is printed in a book it must be correct so perhaps there is a computor programmer around as to why he continous to use erroneos methods for programming with respect to radiators!
Best regards

Quck question, Roy,

Would it matter if I "separated" the whips electrically with, say, 55 feet of coax? (That's approx the length I get for RG-174 coax, which is something like 1/8" in diameter, with a velocity vactor of .66 and working with 9 MHz.) Just a thought, but I don't know whether it has any merit or not. And I am thinking I could adjust that "length" with an RLC circuit through which I sort of "tune" it. What say you? Is this line of thought worth persuing? Or would wiggling he whips still throw everything off?

And I do seem to have a fair abount of patience with this sort of thing. Been working on the current project for about 2 years, had it working on and off, taking it apart occasionally to implement some new retrofit or engineering change. I am on disability, and have nothing but time on my hands.

Thanks for any feedback...

Dave

I just use 1/4 wave whips on mine - one for 2 meters and a longer one
for FM broadcast, mounted on the T-top's antenna mounting plates. Just
something to consider if you cannot find the longer marine antenna that
you're looking for.

Forgot to mention one thing. Don't know if I said this before or not, but
this is of course for receive only. No transmitting with such a cob job...

Thanks,

Dave

1624. Re: Ringo ARX-2 vs ARX-2B - What's the deal?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-23 21:16:51 UTC
From: Jim-NN7K
Message-ID: <eJAJi.186$ih1.116@nlpi068.nbdc.sbc.com>
Source record: 36154

Kevin (and others) What the deal is- that the original ARX-2 (not
De-coupled) allows rf to go on the outside sheath of the coax, allowing
it to become part of the antenna system. The decoupleing stub- with
1/4 wave ground plane radials, forces the rf off the coax below
the radials, allowing 2 features- 1) minimizes rf feedback towards the
rig (eliminates rf burns, in high power, and 2) makes the antenna
radiate simetrically (when the coax shield radiates, it distorts the
antenna pattern, both in recieve, and transmit.) Realistically, it
probably makes little difference, overall, but was a sales pitch,
started by AEA, on its Isopole antenna. Was demonstrated at Seattle
ARRL convention side by side- The coax from the (original) ARX-2
would light a lamp on a RF sniffer, held next to the coax-- the ISOPOLE
didn't! Cushcrafts response was the ARX-2B (and a mod kit for the
ARX-2), that eliminated this coax radiation! You can easily duplicate
the effect with 3- 19 inch pieces of aluminium wire, to the mast , held
on with a hose clamp! (dont forget to also attach that coax shield, at
that point!) Jim NN7K

ok... now if you have a LAW that is different than what is put down in the existing maxwell's 4 equations you must be able to write the equations that make your law different than his. if you can't do that, its no better than a bag of hot air. so show your calculations, write a paper, get it published and show the rest of the world that uses those equations and gets perfectly valid results why we are all wrong.

I saw a large difference when I tested mine. Using stable local
signals to test, I often saw 3-4 S units worth of difference on
the old IC-22u I was using at that time.
But the difference will vary to each installation, length of coax,
etc... It's even possible for the common mode currents to add
in phase and cause an increased gain, but that is very rare.
The decoupling kit makes the antenna work the same no
matter the length of coax, etc..
Well worth the trouble I think.
BTW, I've compared the decoupled cushcraft to the isopole.
The decoupled cushcraft was close, much closer than the
non decoupled version, but the isopole was still the best
by a slight margin. The isopole was probably the best dual
5/8 antenna ever made as far as decoupling the line.
But for the money and slimmer looks, the 2B cushcraft is
pretty good. I used one for a long time.

I'd ignore him. The moron can't even read properly...
I see no text written where you tell Art to shut up, or even write at
a lighter
shade of print for that matter..
I think "John Smith", or "Bret", or whoever the heck he really is,
would prefer
that Art brainwash all the unsuspecting readers into thinking what he
writes

is true fact without question. Who cares if it's total BS or not, it's new!
"John Smith" doesn't care if it's all BS or not, just as long as it's some
new theory that seems to contradict old established theory.
He has shown repeated disdain for proven established theory.
He thinks that being most that wrote it are either dead, or in an advanced
age state, that obviously it can't fit in with the "New World Order" of
code toads that dabble with antennas on occasion.
After all, most lived decades ago. What could they possibly know
compared to a code toad that is living in the early part of the 21st century?

I envision him as the type that probably believes most of what he hears on
Coast to Coast AM..

Did I mention that he's a prime time smartass?
Probably not needed, being you got a taste first hand.
Don't worry about looking like an idiot. Anyone with half a brain can see where that dubious honor really belongs..
It might have to be shared by two people though... :/
But at least Art is not really a smartass. I'll give him that.. He's just
confused... I have much less problem with that, than I do a smartass.
Art is confusing the minds of new or unsuspecting readers with all his "theory" though. Thats why he gets so much flak.
Some of his stuff makes the "EH" antenna guy actually look sane
by comparison.. And thats kinda scary... :/

Thanks, Bob,

I've thought about doing just that. A 1/4 wave on 2m is about 19" and would not require folding down. I was kinda hoping to find some gain which would also match the VHF Marine band antenna next to where it would be, but I can't find anything so far.

Sooner or later you will have to act your age.
The tank circuit is a electrical circuit that is also the circuit
of a full wave radiator regardless of how the extended mathematics and
my work
portrays. It clearly shows that release of energy by shorting the
energy source
is how an efficient radiating system works i.e two energy sources
continuing a pendulum swing
as it were. Attack that if you wish since the books validate that
without reference to equilibrium or Gauss.
It stands on its own. If you end feed a folded full wave length dipole
you will get an answer that Maxwells laws will verify and was tried
out by a guy named Frank who I do not know using NEC 4 antenna
computing program and found to be correct. Nobody but nobody has
presented anything that point out errors in any of this.
Now I come to the second point. I would have thought that radiation of
a 1/2 wave dipole would concurr with that of
a full wave end fed radiator but it doesn't. Why is that? When I try
to feed it at the end voltage becomes a problem
as there is no energy receptical available which is illustrated by the
socalled end effects where the voltage has nowhere to go but into the
atmosphere directly with it being contained to a specific frequence
given by the radiators
length so certainly it does not connect with the tank circuit of a
full wave.
So now we can also take a look at the electrical circuit of a half
wave end fed radiator where we come up with a series circuit but no
evidence of what starts the radiation and in fact the circuit has none
of the character istics shown by the tank circuit and does not provide

any clues as to what creats radiation, this all experts agree upon.
Nobody but nobody has ever been able to describe radiation.
Now based on the parallel circuit I profer the following. Static particles are allowed to rest on diagmatic materials
and possibly paramagnetic materials each of which cannot retain a magnetic field. All other materials are bound with specific electrons that repulse static particles. From the same gaussian laws which when expanded the way I stated
is directly related to present dynamic laws such that on a full length radiator there are particles at rest and I might add decaying.It is reasonable to assume that the instant release of energy overcomes the inertia of the static particles and push them awayby fracturing the arbitary field. Those that do not escape return to the radiator surface
which is now fully occupied with static particles thus forcing the particle to burrow under the surface providing skin effect of decay.
The next release of energy does the same thing but fracture or penetrates the arbitary border at a different place producing radiation other than that of a planar array or any other array not in equilibrium.
As for the half wave there is nothing that suggests any similarity to the tank circuit, no suggestion that energy release is from two energy sources but evidence that there is not one to contain the voltage swings/.
Now the tank circuit shows that beyond the frequency band edges there is a strong dip in filter pass abilities so the radiation is retained within a certain spectrum. In a series circuit the spectrum does not have a pass filter
and infact the end effect is really the escape of energy to the atmosphere without a containment within the desired frequency spectrum so clearly it is not operating efficiently which also suggests that the driven energy is not fully matched to the impedance of the antenna itself which again suggests that because it not resonate in circuit terms the feed line is invaded to correct the situation.
So be my guest. End feed a half wave radiator and a endfed full wave radiator and then compare.
The new shortened antenna from the university of R.I. is a good place to start where those who are familiar with the state of the art state that the feed line has been forced to become a part of the antenna so one has to look at SYSTEM as a whole. Now using the same antenna the wire does not stop at the top but comes down to the starting point by winding in a contra wound direction such the radiator is a full wave length and in equilibrium and by strentch the height of the radiator to remove any stray capacitance that has been added (since the LC ratio of an antenna must be held to) you will find that the new radiator is balanced (in equilibrium), has no end effects and does not extend the circuit to the feed lines and has the same impedance and volume of the original short antenna but with more gain.
With all the above I rest my case especially since nobody has refuted any of it in scientific terms which includes mathematics.

Isn't life good when things come to a successful end such that the
time has come around again as it always does to throw the old books
away of past generations and go with books of the new generation?
Best regards to all

The NEC engine calls standard matrix math routines, so one can replace
the libraries with a multicore library (or, even, with a MPI based
cluster library). This can help a lot on huge models (thousands of
segments)

>
> Todays computers have multiple cores. Even I am using one with two

> solution, I do not want to reinvent the tire again.

Or when you're doing multiple frequencies.

The NEC engine does things in several chunks:
a) building the matrix from all the geometry, including the coupling
between segments -this is frequency dependent
b) solving the matrix for the segment currents - this is a
straightforward (but time consuming) linear equation solving process
c) calculating the field by integrating all the segment currents -
this is independent among the az/el's or near field points in the
output.

So there's opportunities for parallelism in each of the three chunks,
some of which are almost embarassingly parallel (EP).
a) if you're doing an analysis at multiple frequencies, running each
frequency on a separate machine/core is a great idea, since they're
essentially independent.
b) as you suggested, breaking up the output computation (c, above) is
a natural
c) using a multicore or cluster matrix math package can help with b,
above.

Whatever you do, you should seriously contemplate basing your work on the NEC4 engine, rather than the older NEC 2 engine. Sure, you'll have to pay for it, but it's structured better for what you want to do, and more accurate to boot.

Bull. A ham who holds a doctorate and works for MIT provided the
corroberating details.
It is not my fault that your mathematical knoweledge and education
could not keep up with him which is the same for all others on the

thread. Nobody but nobody could fault his mathematics and you call that just "hand waving"?
David it was you who led the charge and consistently stated that you can't apply a time varient to a static field and refused to acknowledge that the math supplied that concurred with Maxwells laws relying only on the fact that it came from your own mouth so it must be correct. Now that I call "handwaving" all mouth and no facts proffered to confirm your opinions or guesstimates. Now you say you should be able to take a "challenge" well I invite any scientifically based challenge some thing I have hoped for in a long while from the self professeed experts and am still waiting.
I can understand opinions from hobbiests you have joined the ranks of ham radio but for those skilled in the art and have gone thru the reqimen of getting a degree or obtaining the rights of a professional engineer one would expect a more factual debate on the subject. If you don't understand the subject then you default your right to critisize.
Now I have Richard firing his nonsense across my bow with the credentials of a degree in geography that trumps all others in the hope that he can get somebody to talk to him.
Have a happy day to all

Art
Science is about building on the foundations of the past and not about throwing away books. The old methods of calculation still work fine, its just that in the light of new knowledge we can refine the methods to produce more accurate results. All of our achievements to date have been built on the foundations laid down by past generations and it is foolish and dangerous to dismiss or ignore any part of history. Never, ever throw away a book - well maybe the ones by Catherine Cookson et al :-)

Are you quoting Gobbels now?

This "golden city on the hill" fluff hardly describes any antenna of
remarkable ability. The alternative is so much misty eyed and fond
desires (superstition) like a pre-teen girl's scribbling into her
diary.

Seems to have worked ;-)

Oh, by the way, it is a degree in English (you know, the country you
hate - now THATS geography).

By the by, I see you still lean on MIT who left here misquoting
Feynman and having mixed up his math (at least you both can have a
reunion when your next anniversary comes up).

Can I anticipate another sob story about how wicked we are here? (Boy,
those "gentlemen of eham" sure stomped your ego.)

Hi Rick

I have just tried an HF 80 metre ground mounted quarter wave vertical in exactly the conditions you describe. The screen of the coax feedline is grounded at the base of the antenna with a copper earth rod into very conductive ground (effectively wet sand). The antenna impedence and performance appeared identical whether or not quarter wave radials were attached or not.

At a previous location with less conductive soil the radials did make a difference.

A couple of quarter wave radials can certainly be effective and easier to run out than a multitude of shorter wires circling the antenna. As usual it all depends on the local conditions at your location and what you have available to work with.

Larry,
Those marine antennas are really pretty, and I figured you wanted one
to compliment the existing one. I found at least one guy that uses his
VHF marine antenna on 2 meters, and says the match is better on 2 than
marine. Check
"http://cruisenews.net/cgi-bin/mmham/webbbs_config.pl/noframes/read/1372"
and maybe you can contact him for more info.

You can answer most of your questions by modeling it with EZNEC. The free demo program available from http://eznec.com is perfectly adequate for the job. After going through the "Test Drive" tutorial in the manual, I suggest that you take a look at the d_Cardioid.ez example file to see how you can model an array with an ideal feed system. What you should do is model your array in a similar manner, with two perfect current sources. With the sources equal in magnitude and 180 degrees out of phase, you'll get a bidirectional pattern, and it won't be sensitive to frequency or element spacing. But then see what happens when you change the phase and/or magnitude of one of the sources just slightly, to simulate what any real phasing network would do. What happens to the pattern? Look at the feedpoint impedances at various frequencies, and see if you can figure out how you'll make a network to deliver the correctly phased currents into those impedances. Another thing you can do is try phasing them for a unidirectional pattern by giving the sources a relative phase angle of 180 degrees minus the electrical spacing of the elements (which of course will be different at each frequency). You can get a nice looking pattern, but you'll find it extremely sensitive to frequency and element spacing.

EZNEC will give you the opportunity to turn some of that available time into an educational experience. I guarantee you'll learn a lot in the process. If you want to learn even more about phased arrays, see Chapter 8 of the _ARRL Antenna Book_. The phased array section was completely rewritten and updated for the latest (21st) edition.

Fully understood. Odd thing is that 73 magazine used to make a good
living by printing details of various antenna
building and I admit I built a few of them.Ihave described the
modifications needed for the new university antenna and for some
reason see no reason to build it because it is a dud. I know you built
the university antenna to check it out for yourself but I don't know
of anybody who did the same thing to verify the claim. So it goes for
the simple modification I supplied which if I am wrong gives loads of
ammunition to every body to shoot me down once and for all with
factual details but they seam scared to search for the truth. In the
absence of knoweledge usually resort to insults and name calling and I
see you got such a burst today. Remember that time when a guy appeared
with his new NEC 4 program and wanted to model a simple arrray I
supplied? Nobody would help him in checking things out and it took a
personal E mail from somebody who did not want to be identified to

help him with the proper useage of the program. It proved the veracity of what I had supplied dispite the lachof assistance to prove me wrong.
As yet nobody with knoweledge of the state of the art has taken me on with respectto what I have discovered. I have had posts given where I believe the central theme was poetry, others who said they couldn't understand despite posts given by a Doctrate holder, ofcourse there are many like the blasting that you just got which should invite back the multi posters that decimated several newsgroups. What I am doing is sharing my work so all can enjoy but if hams are satisfied with lesser antennas because of the poor conditions so be it. But to try and stop thespreading of a particular advance to protect their so called resumes as being experts is really hard to fathom. I thought it would be a delight to all if somebody refuted the mathematics given but only silence reigned and then joined by name calling. Look at todays posting, how many were devoid of insults and name calling, I think that they finished up in the majority so what does that say antenna talk by hams?
I am beginning to wonder with the spectrum being in such demand if the FCC would be justified in selling the amateur frequencies since it is certainly not the same when the frequencies were given, a listen to repeaters or a review of newsgroups going ons must fraustrate them very much. After the upcomming sale of frequencies which is in demand by industry I can easily see pressure on ham frequencies which is costing not contributing to the coffers. The idea that we are a public necessity was down graded years ago by industries inovative ideas so hams have a hard time now justifying their position. In the past it was often said that it was amatures that advanced the cusp of the science well we sure are not doing that now!
O well let the discussion move away from mathematical analysis of antennas or new designs and get back to argueing and calling people names e.t.c. so all can participate including those who are true hobbyist that do not wish to concern themselves with the engineering background but who also want to participate in the augument side that most hams relish.
Have a happy day and goodnight

I was recently told that the non-commercial NEC-4 license doesn't include source code. I haven't confirmed this, but it's something you should investigate before purchasing an NEC-4 license if you intend to modify the source code.

You'll also, of course, need a Fortran compiler capable of compiling a multi-threaded application.

Speaking of Isopoles, apparently the outfit that bought the Isopole segment of AEA has never brought them to market. Fair enough. However, there is an outfit called Spectral (from Brazil, I believe) that is selling an "Isopole" that looks all the world in their ads the same as an AEA model. Their pricing is rather steep compared to when AEA was still a going concern. Has anyone tried one?

Fortunately, I still have most of a new 2m Isopole in a box that I picked up at a hamfest a few years back.

Thank you, Roy. Seriously. I've been putting off trying EZNEC out, but guess it's been long enough. Like you say, time to put some of my spare time into a serious learning experience. Thank you for that link, too. Now I have no excuses. :)

I do appreciate your feedback, and encouragement. Sorry if I was being lazy. I really don't know why I've been putting it off, but I realize now that I have.

'preciate it.

Dave

PS: Thanks too for the tip on the latest edition of the ARRL Antenna Handbook. Now I know I need to get that edition, and not an older one.

I have a non-commercial license, and it came with NEC 4.1 FORTRAN
source code.

My non-commercial copy included Source. I can't imagine that getting
only precompiled versions would be particularly useful, unless they're
willing to make a whole raft of versions (more than you get with the
release I got) with various values for the maximum segments, etc.

OTOH, LLL did just change management, so they assigned all the
licenses from UC to the new LLL management consortium, and maybe they
changed how it works for new licenses. The website still says to make
your check payable to Regents of UC

http://www.llnl.gov/ipac/technology/software/softwaretitles/nec.php

And someday, Gerry Burke is going to retire, and whoever picks it up
from him may not be as willing and helpful to, for instance, recompile
peculiar versions for you.

>
> You'll also, of course, need a Fortran compiler capable of compiling a

That would be if you're doing finegrained parallelism (e.g. using a
multiprocessor BLAS library. Several of the strategies (dividing it
up by frequency) could actually be done by a reasonably simple shell
script/batch file that fires off the executable on different
processors with different input files. For my own NEC on a Cluster
runs, I've done the separate runs on separate machines and merge the
output files in post processing strategy.

Let me cut though this BS--straight to the chase; this group would be better renamed to rec.radio.amateur.EZNEC

If eznec doesn't OK it--it just won't work; All which exists here are eznec-appliance users.

However, to some who have already built antennas which work, contrary to eznecs claim they won't, it is quite obvious current beliefs, equations, charts, theories, etc. are in some degree of error ...

The nec engine would need to be multi-core aware. As some have already
pointed out, you would need the source and the ability to modify it ...

At the present time, I'd be surprised if a 64 bit version of the engine
even existed; however, I have not even looked into that.

I've been thinking about putting one or two of those up this winter.
I do a lot of BC band listening along with 160m, so should be
interesting. Trying to decide what directions I want to go though..
I think Europe is probably one direction I'll go for sure, but can't
decide about the west.. I'm kind of leaning placing one basically
towards Asia, but haven't really decided yet..
I've never used them before, so it will be something new to
play with.
I'm also kicking around the idea of a new small loop to use up
there that will be quite large. I want it rotatable just like the
ones I use here at home. Will use heavy PVC I imagine.
My largest small loop here so far is a diamond 44 inches a side.
It's indoors next to me on a rotating stand. Stands almost
8 ft tall on the stand, and almost touches the ceiling.
Uses 5 turns.. Tunes 500kc-2300kc using various variable cap
configs.. Longwave if I tack on extra fixed caps.
I'm thinking about an even bigger one to use outdoors. :)
Maybe double the size of the present one, or even bigger.
I will use it for BC band more than anything, but will probably
rig it to cover 160m at the top of it's range if possible.
I like the loops when daytime BC listening. Very deep nulls.
Some mention using a shielded loop to aid balance, but
I've never needed to here. My conventional solenoid loops
can make a fairly strong unwanted station or noise totally
vanish in most cases in the daytime, when most is received
via ground wave. I want to try the beverages to see if I can
do a bit better at night when the skywave kicks in.
Also maybe be able to hear a bit of weak DX on 160m for
a change.

It seems to be difficult to realize my wish! Nevertheless I will start with an simple antenna optimizer using multiple cpu cores without modifiying the nec-engines (e.g. NEC2 executables). Antenna optimization can be easily parallelized. Every sort of antenna parameters (experiment) could run on different processes and therefore can take advantage of multiple cpu cores.
I will see, how far I can go.

Hi Larry

Cant help you with a specific choice. Be aware though that considering the boat thumps around in the water the antenna will never be always quite vertical. If you run a "gain" device you may find you'll get a more choppy signal and max radiation lobe that never quite line up with the optimum. As an indicator a 5/8 (car mobile) whip in rolling country can actually work worse than a 1/4 wave. (And also in a city/skyscraper area, but for a different reason)

FWIW I do remember a 5/8 over 1/4 wave design some years ago where you could remove the phasing section and above. A handy feature.

Of course if the boat motor is broken and there is no swell it may be good to have gain!

Cheers Bob VK2YQA

And, Art, you haven't posted the mathematics to prove or even illustrate what you believe about this -- which would be valuable to you, as your beliefs are so different from antenna engineering practice and field experience.

You will have more credibility and respect if you post your mathematical proof so that others can investigate your beliefs using scientific methods, rather than persisting in your challenges for others to prove you wrong based only on your prose.

Actually, I remembered in the shower this morning that a 1/4 wave must have a ground plane to work against and the hardtop on which it would be installed is all fiberglass - no metal. Whoops! I guess I have to have some kind of antenna which does not require a ground plane - maybe a 1/2 wave or something similar. Now we're talking enough height that it has to fold down.

I'll follow the link that Bob gave and see what the guy is using. I suppose I could disconnect the marine VHF antenna and hook it up to the ICOM and a SWR meter and see what I get. I guess I should give that a try. I don't need to do anything to try that.

I know that I'd lose some of whatever gain those things claim, as the antenna would seldom be completely vertical, but I've never found that to be all that significant anyway. I just need to have an antenna which does not rely on a ground plane. Since I'm only fishing on lakes, I don't think that is all that significant anyway. I've found that marine VHF gets almost nowhere (nobody around) so I think I'd do better with 2

meters.

I personally have never had a QSO using a simulated
antenna. :-)

It also works the other way. By accidentally violating
the modeling guidelines, I came up with a simulated
omnidirectional antenna with 24 dBi gain. Want to build
that one?

I have gonedown that road also in the past. As one programmer stated
Antenna programs are not perfect and neither are you. They do not
adhere to Maxwells laws
because some have taken the libity to insert assumptions when things
don't work out.
Mathematicians usually find a constant to insert if they are not sure
of mathematical difference
or their mods don't work. You can do that with a theory because it has
not been confirmed but an electrical LAW
stands alone as being correct as it stands. Just imagine using Ohms
law with a fudge factor inserted where you have to insert a fuse to
take care of it! Even when dealing with superconductors there are
numurous provisos with respect to an ifnittessimle length that are
"solved with mathematical technics. With my amateur thesis that is on
unwin@sdsc.edu plus other letters and attillas I wrote down the tears
that the head of the nuclear industry in Russia stated with the
reliance on the computors ability to do multiple equations every
minuite of the dayin the hope that one answer fits the bill or at
least it will if you add constants where it deviates from what you
want!
However the assumptions used in this case finally worked out for 100
years and where it doesn't work
in the present computor era then you didn't follow the restrictions
that come with adding assumptions

John you are preaching to the converted! Cecil is known for standing
his ground
on technical matters despite the howls and catcalling. His posts
easily exceed a hundred or so
because he rarely get a reasonable technical response in this group.
That ofcourse takes a lot of tenaccity and visits to the texas
university library and I could never do that because the group would
attack the library contents. I prefer to hammer on the same subject a
bit over time for several years as you can see in the archives on
Gaussian antenna, this seasons you to laughing at the comments instead
of taking it personal because it becomes obvious what the technical
level is of the poster. No problem hobbiest having thought and
theories and stories of magnificent performance of a wire that rests
in a gutter and then drops to the ground so that they are part of ham
radio that produces statement that "my antenna is best because every
thing I hear I can work" Or "every thing is known about antennas"! or"
we already have good antennas so why do we need to know how they

work". But when they take on a technical mantle without the require
engineering regimen it can be very very funny.
Regards
Art

1662. Re: Questions about a 2m J-pole

Source record: 36092

OK, I've built my J-pole and it's looking quite good. In the end, I
went for 22mm copper tubing as I had some spare. I've still not
decided on the coax though. I've measured the run, and I'll be needing
12 meters (39 feet). In addition to the RG213, I've managed to find a
source of 'low-loss mini 8' (RG-8X). The RG213 is £1.40 per meter, and
the RG-8x is £0.65
per meter. Is the RG213 worth the difference on VHF?

Thanks for all your advice and help.

Art:

Far too many times, I have been present during discussions where a "newbie" (one not well schooled in the amateur-antenna-religious-order) discusses some weird idea(s) he proposes to set in aluminum/copper and insulation. And, far too often I have seen him discouraged and "converted."

What the heck, let 'em try it, someone just may hit the lotto!--but then, I have seen the "hidden errors" in current knowledge.

Frankly, I love the fact data/knowledge exists which has been so explored as to let us, immediately, construct "canned antennas" with excellent performance characteristics (or at least functional/usable characteristics.)

Is it so difficult to allow some to explore less conventional designs, methods, ideas, experiments? From what I have seen, most who explore these "dark arts" have already explored commonly constructed antennas and yearn for some diversion (or, perhaps wish something for a special purpose--for example stealth!)

For those who walk to the beat of a different drummer--I'll keep the light on for 'ya, 'ya all hear? Just have the fortitude to take the slings and arrows ...

Regards,
JS

So whose facts do I use to build my antenna?

Do I use facts that I have already used to build operable antennas that function as claimed, or do I use facts that to my knowledge have not ever been used build an antenna, but facts that only make for almost impossible to read text in a Usenet group?

It doesn't define one as close minded to note that extraordinary claims require proof at the same level.

wouldn't simple proof be a lot easier than declaring all who disagree as enemies of one sort or another?

Build one of those bad boys, put it on an antenna range, test it out and let the decibels fall where they may. All else is just netnews s/n.

Proof would shut us close minded ones up would it not? Then the antenna will become status quo, and we will rush to defend it.

Morad Electronics in Seattle, Washington makes the 156HD Marine Antenna
that is used on better than 90% of the High Seas Fishing Fleet that
fish the North Pacific and Bering Sea. (Deadliest Catch vessels)

Morad also makes a Ham version of the SAME antenna, called the 146HD.

All the Morad Antennas were designed by the legendary Marine
Communications Engineer Eddie Zanbergen (RIP)

I am not affiliated with Morad Electronics, but have installed and
used their products for the last 35 years. There isn't a more
rugged and weather survivable Marine Antenna than those in the
Morad Product line.

SNIP
I would go with that one if I were you so you keep apace of your
knoweledge level.
You could look in the archives for this year and look up the "Davis"
mathematical
solutions contribution once in a while so that you can upgrade in the
future
You can work everything that you hear now so hang around until
somebody makes the one I suggested
but then they may be competition minded and not tell you of the work
they have done for themselves!

I'll jump in here without knowing much about the program, but in
general having the Fortran source code doesn't do much to solve your
problem. The function calls to the run-time system is where the
problems will occur. Unless there are versions that support multi-
processors, you are still screwed.

Sorry to hear that Dr Davis must have removed his comments and data
after the group teed him off
one too many times. They are in my ongoing patent requests so sooner
or later they will
come to light again. I think I may have reproduced it on the
unwin@sdsc.edu pages but I am not sure.
Ofcourse I did have some of my work overchecked on this by professor
with a P.E. who did it via NEC 4 before I placed my first patent
request since each request at the PTO is around $500 and that is only
the beginning costs
so it pays to have the basics reviewed without your presence so you
are not throwing money away' especially if you have a series of
patents going thru based on the original discovery.

While BPL could indeed be rammed down our throats, the technology itself is inherently flawed. Other technologies to give out better broadband access at less danger to the consumer,(BPL does not survive trips through transformers, so we'll be getting our BPLband through some pretty high voltage lines. Don't worry though, those isolators work just about almost all the time!

IOW, as you mentioned, the marketplace will take care of all that.

1676. What you always wanted to know about fox hunt antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-24 18:12:38 UTC
From: "Helmut Wabnig"
Message-ID: <f6vff3huf8e3s79m0bd020ofvkjkrqk074@4ax.com>
Source record: 36106

Here is the text without the images, please download PDF from
http://radiation.weblife.at/main

####################TEXT##################################

What you always wanted to know about Fox Hunt Antennas,
especially the "Tape Measure Antenna".

There are several webpages describing how to calculate the basic
design parameters of three- element Yagi antennas and practical
examples of how to make them out of various materials.
The classic design page is by Joe Leggio, WB2HOL on the webpage
http://pages.videotron.com/ve2jmk/tape_bm.htm Please read, I do not
repeat the contents.

The design is made of PVC tubes and tape measure pieces as radiating
elements. Note the taper of the elements. It seems that the second
element from the left, the radiating dipole, is tapered more than an
estimated linear decrease. Further note, that the center element is
positioned more to the left. We will soon discuss what that tells us.

(Image from the Leggio page)

The Leggio design is based on non-conductive boom material. Note that
the front part of the antenna is quite long as seen from the center
dipole. The distance will only be correct when we use an insulator as
boom carrier. On the contrary, the left half is shorter, and there is
the cable running along the center from the radiator to the leftmost
element, the reflector. The non-conducting boom design is defunct now,
on that part of the antenna. Therefore the calculated element
distances will have to be changed. There is no need for a galvanic
connection at the center of the reflector element, because the voltage
in the center point is zero anyhow and no current will flow between
reflector and boom. So we have a boom design of half a conductive and
half non-conductive material, effectively. All electromagnetic waves
shorten their wavelengths when entering a medium, and waves travelling
along a conductor have a shorter wavelength than in free space.

To aid our calculations we may use the software YagiCad4.1 from here
http://www.ipass.net/teara/kq3.html and a ready made recipe from
there http://home.att.net/~jleggio/projects/rdf/tape1.zip
That little gem can be learned and mastered within 15 minutes, while
also very fine, good and marvellous pieces of software like
http://home.ict.nl/~arivoors/ will take you five weeks to master. For
the design of our fox-hunt 3 element yagis, the YagiCad is sufficient.
As a homework, go and enter the original WB2HOL data into YagiCad.

Surprised?

Well, let me skip and leap forward. I do not intend to write a YagiCad turorial here. To proceed with the story, and come to the more interesting part, let me tell you how my copy of that antenna worked: it did not. It was clumsy and heavy because good PVC is not available here, and I of course scaled the design from the 146,565 mentioned by Joe Leggio up to 150 MHz by percent-wise shrinking every part. Time to look around.

The Cebik pages, W4RNL.

May those pages last forever: http://www.cebik.com .
For the topic chosen we must read http://www.cebik.com/ao/ao1.html .

Let us jump into medias res:
(Image from Cebik page)

Foxhunting requires good front-to-back ratio, and not maximum gain. In most cases the frequency used will be given and will not change, so we may design an antenna with our desired frequency as center frequency, using YagiCad. By varying the overall length of the antenna we find out that length influences gain. Positioning the centre element, the active dipole, we notice that the position influences the forward-to-back ratio. Because everything influences everything else on an antenna, the observations we make will not be as clear from the beginning , but after a while of experimenting we get the feeling. Let YagiCad do the optimising. Compare the results with the recipes given by Cebik. Note, that both sources assume a non-conducting boom, and the obtained numbers refer to isolated elements
in air.

What happens when we use an antenna a few megahertz above or below the nominal design frequency? Gain will not change much. Impedance will change somewhat, but we are less concerned about when doing fox hunts. What changes most, is the F/B ratio, actually it changes catastrophically if only a few hundred kilohertz off center. That quickly renders an antenna useless, and especially beginners then claim to hear signals "from all directions". Impossible to distinguish between direct signal and reflections and the reception from 180ï¿½ backwards. And do you really expect your home made antenna to be as good as the data from your calculations? Do you expect the wire skeleton to resonate precisely at your target frequency? Remember, even the coax cable to the rear has an influence, and what if your boom is constructed of metal?

Optimizing F/B ratio on real antennas.

You guess, just make the center element, the driven dipole, moveable. The direct advancement is that we can equal out manufacturing tolerances and practically unknown parameters of small influence. But the main achievement is that we can precisely adjust the front to back ratio for our desired frequency. We will never be able to reach the 57

dB which theory promises, but we get the best out of our real existing home made marvel. Then we may be able to do a nice observation.

A tape measure antenna with metal boom, working at the correct design frequency, and adjusted to best F/B ratio at 150 MHz.
Compare the setup with the Leggio and with the Cebik images.
To the left (out of sight) is a noise generator, transmitter PA and a transmitting log-periodic antenna. The analyzer displays what the receiving antenna delivers.

What does this tell us? Obviously the
Leggio Antenna is detuned from its
center design frequency. It may work
or not, if you copy the design for your
purpose. Make the center T on the PVC
boom moveable, success guaranteed!

Final remarks.

'Nuff said, just a few additional pictures.

The slider, top view. Side view,
elements mounted.

Do we need an attenuator? Absolutely!
In some cases an offset attenuator may be recommended, especially if you know the precise frequency of the target, the "fox", but sometimes we are better off with direct frequency equipment, especially when searching for radio interference sources.

Element mount (director)

To the right and below: Complete fox hunt equipment, antenna,
attenuator
and receiver.

By Helmut Wabnig, OE8UWW, Sept. 2007.

> to happen.

Oy! Take a deep breath Ed! Tisn't that bad, and you're being way too pessimistic. Right ends up winning out, sometimes just takes a while.

At any rate, it isn't 300 million people, It's just those who can't be served much of any other way. And that isn't too many. Even then, it isn't going to serve those people, unless the utilities run fiber until the "last mile". BPL does not survive trips through the power lines very well, so fiber is needed almos to the house. And the fiber is what we want. And once the fiber is there, why not use a technologically better system to deliver it that last mile.

Hey! I have an idea. Give me that good fiber signal!!

Sometimes I think that BPL is just a trick to get Power utilities to string up fiber so that private sector companies don't have to. Fiber up, and once BPL falls on it's face, private companies come in and start distributing fast broadband.

> Instead of fretting and whining, why not try to come up with work arounds?
>
> For instance, digital phone is probably much more able to handle the BPL
> noise than analog phone. Get busy! <G>

I'm not sure that digital phone would be better. You'll have one S9+ signal interfering with what will almost certainly be a much weaker digital signal.

Hi Arthru,

"Not sure" seems to be the keyword. Lack of details, lack of
background, lack of examples, and lack of understanding (no shortage
of ersatz thinking) reveals to others what is not obvious to you:
an email address is not a web page

But we all know what you don't mean. :-0

Yes, it must be tough to be a towering generous in exotic theries when
you stumble so often from tying your gaussian shoelaces together.

Dear Michael from the past I was called every name under the sun on
past patents
This time I gave the basis of the mathematics, I gave a array of full
wave
elements that was checked independently on this newsnet. I also put
up a page
with the data and drawings from a static field ala Gauss on to a
dynamic form
where it can be verivied by computor programs.
All I got was jeers and insults there is nothing more that I can do
other what I have done

I can't make you make one even with instructions and I am not giving
out gifts.
Oh and you got the benefit of Dr Davis's mathematical analysis to boot
before the group dissed him to.

To me, no, it isn't worth the difference in price, nor the hassle in handling the thicker coax. Were I working weak signal modes, it might be a different matter, but then I would use hardline or 9913 at the minimum.

Using Clusters, remembers me to my past university days. Indeed, I used up to 20-60 personal computers on the computer centre, to compute a ray-tracing movie. That was in the 90´th.
How do you handle the process communication? And how do you handle the results?
There are more reasonably possibilities to speed up antenna calculation and in special case of course optimizing too. The reason, why I am want to speed up is, that antenna optimizing takes a lot of time. I am often using the optimizing tool of 4nec2. It is a very nice feature of 4nec2, to parameterize the antanne elements using mathematical formulas. Anyone here, using this feature extensiv?
Aziz

Only you can answer that question. For 12 meters on a
flat line on 2m, RG213 has ~1dB loss and RG8x has
~1.5dB of loss. (LMR400 has ~0.6dB of loss.) Is
double the price worth 0.5dB to you?

while this may be good about yagi antennas, that is only one type of antenna used in fox hunts. they are usually good for long distance hunting, but tend to be too broad for close in work. loop/sense antenna combinations with a deep cardiod pattern null are another type that is very useful, even plain loops with good side nulls are helpful. then there are also the various forms of 'doppler' antennas. beside the classic 4 vertical doppler design that is usually limited to car top applications there is a simple 2 vertical design that is good for use on foot. and example of that is at: http://www.k1ttt.net/technote/doppler.html

Actually, the reverse has happened several times now
in quantum physics. The math (standard model) has predicted
bizarre, seemingly impossible things, e.g. entanglement
(Einstein's spooky action at a distance) which was later
proved by experiments to be a fact of reality.

You can find some pretty brilliant physicists who will
state that the QEM model has never been wrong no matter
how unbelievable the predictions.

A million visions hit me where the status quo is unusable--college dorms, hotel rooms, camping grounds in national forests, secure-elite-gated communities where "keeping up with the joneses" is in vogue (and, I am stuck in one--for a bit anyway :-( ), a beach, etc., etc.

I have already stated, canned antennas and the software to define them have a REAL place ... it is only the idiots who shout down everyone else who are in question! Personally, I need the art of small/stealth antennas to expand ... I can't believe I am the only one; I am just more vocal to their importance.

I have already had complaints about the American Flag flying on my 50 ft. pole, so far, NOT flying the flag has appeased the "complainers"--go figure! Any day now, they will eventually notice the pole is still there. Then I'll be stuck with the DLM posing as a drain pipe ...

And, there are errors and missing sections in our complete understanding of antennas, em/photon radiation, etc.--those who will bother to examine the evidence already know this--those who are either unable or unwilling to do so never will.

Regards,
JS

Cecil:

How come I already knew you would be first to propose an argument worthy of consideration/debate? :-)

I spoke boldly, and of course, in too broad of terms--the reasons for such I have already stated.

However, even Einstein would admit (well, if he would allow me to speak for him) that there is "something too all this, alright. However, by the shear lack of a simple model to explain it all--we still are only seeing the tail on the elephant ..."

And, by the way, thanks for the wakeup call.

Warm regards,
JS

I've told him that a hundred times... He won't listen.
How does he expect anyone to give his antenna much of a
chance when the "theory" he provides is generally caca, and
he refuses to build an actual working antenna to demo and test?
What a load of @#$%...
Art and his groupies just don't get it.
It's not that anyone is against new ideas, antennas, etc,
ad nausium.
Just don't feed us a turd and call it a steak if one can't even
take the trouble to build a working example to test. :/
If I had some new whiz bang antenna cooked up, I would build
and test one first, and then talk about it later if it actually was
proven to work.
Art goes the other route. He talks a great storm, but nothing is
ever produced to actually test in the real world.
As far as I see it, that is no way to live.

This comment isn't re noise with the Beverage, but I believe it might be found interesting to those interested
in Beverage antennas. Below is a quote from an article I published a few months ago in QST.

The Beverage Antenna in WW2
by W2DU

As a monitoring officer with the Radio Intelligence Division (RID) of the FCC in Hawaii during WW2 I was
privy to some interesting situations. Our State Department was of course aware of the operations occurring in
the Pacific Theater. The people there were also aware of the propaganda being spewed by the Japanese
short-wave broadcasters. But State was curious concerning what the Japanese living on the homeland were being
told-were they being told the truth, or the same propaganda as told on the short-wave broadcasts, or a totally
different story. State asked the RID to determine whether we could obtain such information.
We cruised the AM broadcast band and found several nighttime signals from Japanese mainland stations, but
most were too weak to copy. However, JOAK, Tokyo, on 640 KHz was S9, but there was a problem in copying it.
KFI, Los Angeles, was also on 640 KHz with an S9 signal-copying intelligence from JOAK was impossible. How can
we eliminate, or reduce KFI's signal level. A Beverage Wave antenna, perhaps?
We then proceeded to the northern portion of Oahu and constructed a Beverage one-half mile long, five
feet above ground, aimed at Tokyo, and terminated with a 1000-ohm pot resistor to ground at the Tokyo end. We
discovered that by varying the pot resistance we could null the KFI signal to almost zero. The resistance
terminating the Beverage that produced the null was around 600 ohms. Because the matching resistive
termination rendered the Beverage a traveling-wave antenna with no standing wave, the signal from JOAK was
terminated by the input of our receiver, while the signal from KFI was dissipated in the matched resistance at

the Tokyo end of the Beverage-no KFI signal reflected toward the receiver. Voila-JOAK was perfectly readable
for recording!
We sent the first recording to Washington, and State was delighted-requesting that we continue recording
JOAK continuously. Consequently, our recordings were flown daily to Washington from Hickam Field in Honolulu.
We were left in the dark concerning the information on the recordings, and how it affected the War effort,
because State didn't share it with us. But it must have been pretty good, because State was on our case every
day to make sure we sent them the recordings.

I have built them no problem but I am not going to give them away to
people who arenot interested in them.
It is no problem to me if you don't make one. Listen out for me when
it gets cold on 160 meters. I have a rotatable one about 2 foot square
that will be on the tower but at the moment I am adding to it to make
it an all bander maybe all frequency with two rotators for horizontal
and vertical radiation. But then if you can't hear me then you can't
work me.
By the way large ground planes are not in vogue anymore since they
have lost their uses. No I anm not going to bring it to you so that
you can see the test or operate it so you will have to continue to
call me names as usual
By the way John E Davis works is still in the archives, he has not
removed it for people trying to find it.

They do make cameras... You can take one to a test range
and post the results.

> It is no problem to me if you don't make one.

Thats good, cuz I prefer full size antennas...

>Listen out for me when

If you put out a decent signal, I should hear you.
I'll be out in the country using big antennas.
Heck, I already have a full size 160m dipole up there.
I was there Sept 1... I converted my old 80/40 dipoles
to add two more bands. Now I have 160,80,40,20 dipoles
on a single feedline. I eventually plan some type of
vertical for transmitting. Probably a wire running up a
tall tree. And yes, I'll be using a few of those obsolete
old radials to ensure the ground losses don't eat my
lunch.
And as you have probably already noticed, I have plans for
beverages up there. I'll have a big small loop too..
If you operate, and put out any kind of decent signal,
I should be able to hear you with little trouble.

> By the way large ground planes are not in vogue anymore since they
> have lost their uses.

What? Ground loss has finally been done away with?
It's xmas in Sept... :/

>No I anm not going to bring it to you so that
> you can see the test or operate it so you will have to continue to

> call me names as usual

As usual, you are not much help. BTW, I don't really recall calling
you any names. Only your posted "theory"... :/

> By the way John E Davis works is still in the archives, he has not
> removed it for people trying to find it.

I don't need to find it. I was here when it all went down.
As I recall, Richard asked him a few pertinent questions, and
he did a runner..
Myself, I think once he finally got a clue what you were proposing,
he decided to duck and cover his rear.. I know he has not been
back to answer the fairly simple questions posed to him.
BTW, if you do decide to get out on 160m to test this antenna,
please do us all a favor and ensure that the feedline is not doing
the bulk of the radiating.
I'll be going back up there in middle-late Oct when the trees
start turning colorful if you want to try it out.

A "John E Davis" Google search of this newsgroup shows nothing posted by John E Davis himself -- only a lot of references to his name, mostly by you, and none of that containing any mathematical proof of your beliefs.

Please refer us to the URL(s) for anything that you, he or anyone else ever wrote and posted directly if such will, by mathematics, support your beliefs that only 1-wave antennas have the required "equilibrium" for "efficient" radiation.

This is your golden opportunity. Otherwise...

Hi Arhtur,

Not worth repeating, is it? Such recommendations fall into a familiar pattern, especially when you can't find your own page.

Well, still and all it bears visiting those archives to read how each of your claims blows your last one out of the air as being the height of stupidity.

Efficient directors are longer than driven elements.
("Time to Burn the books, the early tour.")

More efficient reflectors are shorter than the driven element. (Unless you need two reflectors which are even MORE efficient.)

Short antennas are vastly more efficient because halfwaves are too long. (Good by two reflectors.)

Long (halfwave) antennas are exceedingly more efficient because they were blessed by a heretical disciple of Gauss. (Goodbye directors and reflectors altogether.)

Longer (fullwave) antennas are fantastically more efficient because they....
(Goodbye Gauss, here's another spade of mud in your face.)

Well, at least the jokes aren't all the same, but superlatives are getting stretched thin.

Imagine the embarrassment of this mythical Dr. Phil whose name is being pasted to every theory coming out of central Illinois!

OK, so he only dresses like Dr. Phil. Let's see what he actually had to offer and we find that any support (the word Gauss misapplied) for arT has been spun up out of whole cloth.

Arthru has discovered a button of Dr. Phil's, sewed it to a coat, looked in the pocket of the coat and found a paper, on this paper aRt writes his theory and puts it back into the coat to give us a glowing reference of authorship to the grand Dr from MTA!

For discovery of a button a battle was one.

;-) ;-) ;-) Art spoiler, the following is a joke ;-) ;-) ;-)

These theories of "efficiency" are like the Republicans giving us back our own money - meanwhile the prostituted dollar has plummeted, a barrel of oil has nearly tripled in price, the deficit went sky-hi, and Greenspan is spitting on the White House. Soon we will all be as rich (oops, efficient) as sub-Saharan Africans. At least jobs have picked up in this era of efficiency, it is now vastly easier picking fly shit out of sand.

Source record: 36135

NEC-2 and NEC-2 based programs like EZNEC do a good job of modeling Beverage antennas. (The EZNEC demo isn't adequate for this.) The only trick is making the ground connection. In NEC-2 use Sommerfeld ground; in EZNEC it's called Real, High Accuracy ground. At each end of the antenna, create a semi-circle of radials, a few inches above the ground. For wire length, a free-space quarter wavelength is more than adequate -- the only requirement is that the effective resistance should be considerably less than the termination resistance. The semi-circles should be facing away from the antenna, so none of the wires extend under the antenna wire. Ground "connections" are made to the center of the semi-circle. This of course assumes that there are reasonably effective ground connections at both ends of the real antenna.

I just read that thread all again, even Richards which I have stopped
reading now.
One thing he says comes to mind" the antenna was invented some 100
years ago" but nobody asked where it is illustrated so that they can
see the proof. Rather than pursuing me for data and calling me names
get Richard to show where it is in the antenna books so you can see
the results for your selves. Ofcourse Richard is known for his lies so
I wouldn't hang around to long for his answer because as I stated he
is a liar. He also said he agreed with it all along from some prior
reading but David decided for the moment not to challenge him because
that infered that time can be added to BOTH sides of the equation
which David states one cannot do. O what a web one weaves when they

step down and try to deceiveI But he did get the Doctor to leave in
the same way he has got other experts to leave
purely on the smell of his retorts. I think I will drop out on this
one somebody will surely rake thru all the antenna books of old to
verify Richards fallacioes statments. I am gone for a while to do
things with the antenna before it gets to cold. After reading that
long thread people will never accept that any thing new can come
about
antennas which is why most have departed from that scene and moved to
agitating on newsgroups
Bye Bye, don't know when I will come back so you will have to decide
now who will be the recipient of your arrows and slander from now on.

What do you want to know?

Think about it....

1710. TA-33jr smaller element stuck in larger element.

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-25 00:51:54 UTC
From: Anti-PC <aa8x@wowway.com>
Message-ID: <y86dnWuvK7DtxmXbnZ2dnUVZ_oesnZ2d@wideopenwest.com>
Source record: 36040

I have a very old Mosley TA-33 Jr antenna and one element; the smaller tube is stuck in the larger tube. This is the middle tube and only 3 foot long and about 3/4 inches in diameter with about 1 inch sticking out of the larger tube. I have tried pulling then apart with a bumper jack and vice grips but have had no luck. The elements are not bent nor do they have any dents. I suspects oxidation of the elements is the problem. I have also tried using ammonia but no help. Any suggestions on pulling then apart would be greatly appreciated. .

As a CB'er you wouldn't be expected to know this, but the Amateur
Radio Spectrum has been likened to a National Park.

Hi Merlin

Do you have any suggestions about how the manufacture rates the power
handling capability of that hamstick?

No that is the point. An antenna can radiate no more energy than you put into it. If you do something to increase the field intensity in one direction the field intensity must decrease in other directions. Nothing to debate, it is a proven fact. A fact you will never accept because if you do

you will also have to accept the your guassian antenna is just a delusion.

It is a real shame that you have chosen a knowledge of antennas to be such an important measuring stick for the value of your existence.

Thanks, Jimmie, for the translation. In addition, Cecil directed me to the acronym dictionary, where I also
found it.

Hope your recovery from surgery goes well. I'm still recovering (very slowly) from spinal surgery performed in
April, so I'm well familiar with oxycodone.

news:1190648224.752255.254140@d55g2000hsg.googlegroups.com...
OK, I've built my J-pole and it's looking quite good. In the end, I
went for 22mm copper tubing as I had some spare. I've still not
decided on the coax though. I've measured the run, and I'll be needing
12 meters (39 feet). In addition to the RG213, I've managed to find a
source of 'low-loss mini 8' (RG-8X). The RG213 is £1.40 per meter, and
the RG-8x is £0.65
per meter. Is the RG213 worth the difference on VHF?

Tom,

On VHF FM, a dB or two of signal will affect a marginal contact. In your situation, however, the better cable provides only slightly more than half a dB of signal, hardly worth the extra expense.

I used http://www.ocarc.ca/coax.htm for that comparison.

Other comparison tables and charts are widely available on the Internet with a search for "Coaxial Cable" Loss. The sample table below will line up nicely in a monospace font, like Courier.

Coax Cable Type Signal Loss per 100 ft
Loss* RG-174 RG-58 RG-8X RG-213 RG-6 RG-11 RF-9914 RF-9913
1MHz 1.9dB 0.4dB 0.5dB 0.2dB 0.2dB 0.2dB 0.3dB 0.2dB
10MHz 3.3dB 1.4dB 1.0dB 0.6dB 0.6dB 0.4dB 0.5dB 0.4dB
50MHz 6.6dB 3.3dB 2.5dB 1.6dB 1.4dB 1.0dB 1.1dB 0.9dB
100MHz 8.9dB 4.9dB 3.6dB 2.2dB 2.0dB 1.6dB 1.5dB 1.4dB

> Bob, AA8X

If it's oxidation, try heat. Heat gun, torch, etc. A small amount of differential movement (the outer tube will heat up first/more) may break up the oxidation.

An alternate mechanical means might involve finding or fashioning a cylindrical collar (a scrap of PVC pipe, perhaps) whose inner diameter allows it to slide over the one-inch protrusion of the smaller tube but not over the larger tube. It must be long enough that the inner tube does NOT protrude from it.

With the collar in place and secured with a piece of tape, turn the stuck elements vertical, collar down, and drop them on a cement surface. When the collar hits the cement, the outer element will surely stop, while the inner element _may_ continue downward a bit due to its inertia. (Have you ever held a catsup bottle and smacked the edge of your hand against the other hand? Maybe some catsup flies out. Same principle.)

I have used variations of this method to release stuck telescoping mast sections -- especially useful if the mast was tweaked by dropping.

==========
Although I have never needed to do it myself and risking some negative
comments , may I suggest you explore the following :

Flow water through the inner tube and heat the outer tube (localy) with
a flame torch , in the hope the inner tube diameter remains roughly the
same ,whereas the outer tube will expand such that you MIGHT be able to
pull the tubes apart.

Source record: 36054

Well, I just put up a 'coaxial' dipole, but I'm easily confused...
I got the diagram out and laid it on the floor and then some coax, and some insulators, and some wire, and my big ol soldering iron
(about a 1000 watts used for soldering copper pipes back in my auto company days)
And then I went to wrestlin with the devil...
After the solder smoke and fumes cleared and my eyes quit waterin, I Looked around and lo to behold it was a dipole...
But the durned coax was runnin from the center to the rig and the wire wuz runnin from one end insulator to tother one... Didn't look nothin like the diagram... Well, I'm not one to go against the current so I decided to put it up anyways just for fun...
So, I gets it up and I goes and checks the swear thing they all talk about...
Seems there is a problem...
First I sets the swear meter to forward and adjust the knobby thing so it reads full scale...
Then I tries the reflected setting and that's when the problem begins...
The needle deflects all the way to zero and when I looks at the funny looking Bird chart with the kinda diagonal lines running up and down, that says my swear ratio is 10 to 1... Looks like this < 1.0:1 > on the chart.... Guess the printer made a typo...
Well, I decided to see if I could hook up with anyone before I pulled it back down... There wuz this fella with a funny call sign, 3B7C answered me... Now I need an dipole that will let me talk to Frank over in Franklin County, so this coaxial dipole just ain't doing the job at all...
Guess I gotta start all over agin...

Absolutely. Build and test. Get on the air and work. Put one up on a range and produce some numbers. Publish the numbers. Silence the skeptics. Convert them.

I always kind of wondered about the accusations thrown about here. If they are true, there there appears to be a sizable group of Hams (and apparently EE's and physicists too) who want to be using antennas that don't work very well. They want to use inferior antennas so badly that they squash any attempts at advancing the technology by others.

Yeah, right!

If I could put out a better signal by sticking a wire in a bagel , I'd be doing it in a minute. 8^)

I really think Arts game is to try to get someone else to do his work for
him. If not that he is suffering from delusions of granduer. Sad thing is I
have heard Arts story before in another time and place. I knew a guy that
was truly a mechanical genius but wasted it repairing bank tabulating
equipment back in the 60s & 70s when everything was mechanical. When he
retired after everything was taken over by computers he got interested in
Ham Radio, particularly interested in antennas. Many of the mistakes he made
are the same as Arts. The same mistake about efficiency.

Message-ID: <46f929ba$1$26339$4c368faf@roadrunner.com>
Source record: 36063

A few years ago I was visting with friends down in FL. We had traveled all over the state seeing a lot of sights and fishing. While we were fishing off of a long bridge a couple of hams came out and set up equipment on each end of the bridge. They had installed a matched pair of yagis, one on each end, and was trying to determine the minimum signal it took to span the bridge(a 1/2 mile more or less). The antennas were fastened to a rail that extended the full length of the bridge so the first thing that popped into my mind wa what if the rail was the boom for one long yagi with a driven element and reflector at each end and the rest of the space between populated with directors. Would anyone care to model this.

Jimmie:

Actually, you make a good point. But, I think we are all guilty of it;
or at least I am, I tend to try to focus attention on my personal
antenna endeavors/experiments/needs.

Not everyone needs a perfect, small, highly efficient, stealthy antenna
... but then, not every needs a stacked pair of 5 element yagi-udas'.

And, mistakes? I am looking forward to the day I have made 'em
all--maybe then I will get relief from having 'em pointed out to me! ;-)

Honest question, does it matter whether the objective is a strong ground wave as in AM broadcast or skywave as in amateur operation?

I am installing a Hustler 4BTV this fall and have put down (so far) 16 radials that range from about 18 to 35 feet in length due to my servere space restrictions. I may add 16 more later this fall as an experiment.

I do not, sorry ..
I only pump 65 watts into mine but from looking at the way it's made, I bet
it could take 1,500 watts.
However, I do not think that I would like 1,500 watts output That close to
me...

It is a 7 foot antenna, stacked 5/8-5/8-1/4, I think. I do know that it
puts out a really flat pattern (I do not chat much on 2 meters with
airplanes)

Hi Merlin

I was actually curious about the meaning of the "DC" they use to define
the power rating of the 2 meter hamstick.

No, the local ground losses effect the efficiency the same no matter
what skip type,
angles used , etc..
It will be equally weaker in all directions and angles if you add more
ground loss.
The pattern will still be the same in all directions, as all angles
suffer equally.
Same pattern, just less field strength if you add more ground loss.

Hi, Nate -

The skywave is important not only to amateur operators, but even more so to the nighttime coverage of stations designated by the FCC as Class A AM broadcast stations (the former "clear channel" stations).

However a poor r-f ground system for a vertical monopole radiator will reduce the radiated field at ALL elevation angles including those producing a useful skywave-- not just in the horizontal plane producing the ground wave.

> you will also have to accept the your guassian antenna is just a delusion.

If you look at the field of a antenna that isr radiating an equal
amount in all direction
the volume of the radiation consists of usefull energy in the form of
radiation.
If another antenna with the same energy input provides a radiation
field in all
directions that is equal but at a larger radius than the prior antenna
field the the latter antenna has gain
over the prior antenna.
If you compare any fractional ground mounted antenna with a full wave
antenna the radius of the field
willhave a difference of aprox 3 db and the resistive impedance will
have a ratio of two to one.Note that gain is a measure of one radiator
level against another and is no way a distorted field of radiation
that has been manipulated by an additional near by radiator.
A ground plane does nothing more than balancing the circuit provided
such that current does not meander back thru the feed line and a
ground plane is only necessary for a fractional wavelength circuit to
balance the circuit as a whole. It eats up energy that would normally
provide radiation in a circuit such as a full wave radiator. Without a
good ground plane the impedance to a fractional wave length is
difficult and usually not efficient and a lot less than that of a
radiator that does have a good ground plane which is around30 ohms
resistive which is 1/2 of the resistive impedance of a full wave
radiator.
As far as the Gaussian antenna it is not an illusion to those with an
engineering background.
For those without an engineering background to enable them to follow
the logic do not have
the know how to discredit anything and certainly can not measure the
quality of life of those
with understanding.
If you cannot follow the science of antennas then you are doomed to
be a follower, never a leader.
and certainly not a judge.
I'm gone for a month or so and will not be using this newsgroup during
that time.
Will be back in the fall

A penetrating oil (as has already been suggested) is a good trick.

Then, with a rubber mallet, gently, but firmly, strike the outer
conductor (where it covers the inner conductor)--with the conductor
placed on a firm surface (hardwood, etc.), all the time rotating the
conductor betweens strikes.

Has worked EVERY time for me!

Hi All,

Since Artifice has left us with his errors intact, they can be resolved quite simply before he returns later with more interesting dismissals of his previous incarnations of "the truth."

On Tue, 25 Sep 2007 17:34:22 -0700, art <aunwin@insightbb.com> wrote:

>If you look at the field of a antenna that isr radiating an equal
>amount in all direction

This volume, then, contains a fixed energy. Fairly simple stuff as it happens 365.25... days of the year with the sun. Within the arc of any orbit, there is so much energy from that same sun [hearing the scrabbling of little feet in the cellar insisting stars and such fill the void, I will simply bait the traps with better cheese].

>If another antenna with the same energy input provides a radiation
>field in all
>directions that is equal but at a larger radius than the prior antenna
>field

It doesn't need to be another sun, but if our "creater" insists, I will return to that heresy.

Anyway [gad this is abysmally distant from SWLing and QRM - Dirk, you can't possibly still be with us can you?], we have the same energy within the volume of a larger orbit. Naturally, any inhabitant at the original orbit must be wondering about this state of affairs.

Well, this latter Sun provides the same energy (unless more energy is added, courtesy of our Great Decider bombing it with hydregen bombs in the chance of killing Osama Bin Forgotten).

Um, sorry for the parenthetics, but Arty has never exhibited a very good command of English - I suppose this means I will have to examine both pair o' doxes.

> the the latter antenna has gain over the prior antenna.

In fact, this is true in the classic engineering sense - to the degree of negative gain. Given the obscurity of this missive of his, we must judge this fact escaped him entirely.

To illustrate, same sun, same energy, different orbits, we return to the original orbit to find less sunlight at noon (it has been

squandered to fill more volume). Any gain predictions are found in the debit column of the account books.

---------- Part Deux ----------

OK, so somehow we nuked the sun to achieve this new golden age of illuminating the expanded cosmos with the "same" energy (see how myths are born?).

The inhabitant at the original orbit now sees a brighter city on the hill. His sunburn is manifest in a cancer several years later (blame technology). The inhabitants at the outer orbit now enjoy the prospects of a future temperate climate (once the global ice shell melts).

As we don't know the particulars of the orbit (Arty is never very useful about providing facts that matter), they could be orthogonal - or at least the traditional scientist (providing he has copies of those books burnt by devotees of this "church of gain") would have to allow for any point on the surface of a sphere.

However, if anyone is still reading this, what have been described were TWO Isotropic antennas. As such, the only gain achieved is by nuking the sun (cost $1 trillion per election cycle). In any interpretation, no gain can be assigned to any antenna.

Of course, we all know that.

---------- Section C ----------

>If you compare any fractional ground mounted antenna with a full wave
>antenna the radius of the field
>willhave a difference of aprox 3 db

As I've cautioned Arty in the past, we know what you don't mean - and the light at the end of this tunnel ... we will skip the remainder of doubling cliches here.

Arty is going to disappointed to discover that once again (always) the facts he showers upon us are diametrically opposed to the fundamentals of his proposition. Yes, there is a 3dB difference, but it certainly doesn't favor the full wave (sic) antenna.

> and the resistive impedance will
>have a ratio of two to one.

Fractional/Full-wave? Not even close - unless this is expressed in non-linear, 18 dimensional, gaussian string mathematics. It isn't given that the full mathematical treatments of the total output from Art wouldn't fill the back of a business card.

>Note that gain is a measure of one radiator
>level against another and is no way a distorted field of radiation
>that has been manipulated by an additional near by radiator.

I can only wonder if this fractional ground mounted antenna is on some crystalline planet circling a faint red dwarf.

>A ground plane does nothing more than balancing the circuit provided

Ground mounted and ground plane(d) is not the same thing. If we are to divorce this analysis from the distortions of ground (as in the ground of earth) by mounting it in a ground plane (hung in free space); then this 3 dB gain is going to evaporate like the White House promises of a green card to migrant workers.

> If you cannot follow the science of antennas then you are doomed to >be a follower, never a leader.

I suppose this admission will inform all future announcements.

>Will be back in the fall

A dollar short and an equinox late informs us now.

My bets are follow ups in a very few moments ;-)

Sure Richard, I'm still listening in on this thread; I'm now thinking
about a 518KHz Gaussian antenna... :0)

BTW, it has been raining over here for 2 days, and the QRM levels are
still fine!

I have also done the following experiment: Instead of the commercial
"magnetic balun" I was using, I have now rolled my own 1:9 unun. The
main difference with the MLB is that the unun has isolated windings.
The primary is grounded to the earth rods, the secondary is grounded
via the receiver. I thought this was a better solution with regard to
ground loops.

Maybe it's the same kind of gain that causes
reflections from non-reflective glass to be
brighter than the surface of the sun. :-)

----

art -- the difference in the gains of ground-mounted monopole radiators of different heights is related to the height of the monopole, and the effect that has on its r-f current distribution; therefore its radiation pattern.

The link below leads to a pattern and gain comparison of several monopole heights commonly used in commercial AM broadcasting, over a perfect ground plane.

Note that a 1/2-wave, ground-mounted monopole for these conditions has a pattern and gain identical to that of a 1-wave, center-fed dipole in free space. Also note that there are three radiator heights taller than 1/2-wave, whose gains are higher than the 1/2-wave (or a full wave in free space).

In all cases, the area under the curve is the same for each radiator plotted (mind the dB scale), showing that for a given input power each monopole radiates the same total power into space regardless of the shape of its pattern.

No nearby radiator was needed or used in the generation of these patterns.

So there's something for you to consider while you're gone for a month.

Source record: 35949

Hello,

I am searching for an antenne optimizer based on NEC2/NEC4. I know the
well known (and best useful) tool 4nec2 (my special thanks to Arie).
On some antenna optimizing problems, using the traditional hill
climbing method (gradient method) fails due to local minima problem.
The optimizing function "evolve" gets more usefull results.
I would like to try some another antenna optimizing tool. Are there
any other antenna optimizing tools based on NEC2/NEC4?
Many thanks for any hints.

Regards,
Aziz

Hello Walt, Dale, et al

I thought we worked this out years ago.
The parallel-resonant network of the stubs lowers the SWR some very near

resonance by oscillating at the driven frequency and storing the small amount of energy that would be reflected back otherwise, but a driven circuit won't oscillate very far from resonance, and it does nothing for bandwidth. That's due to loss, as Walt proved long ago. Increasing the diameter of the radiator, as Walt pointed out, does work. There was a good recent QST article on just such an antenna.

It would be interesting to follow the change in VSWR as you add individual radials. Some years ago, there was a discussion of adding radials until the VSWR stopped increasing. This was based on an expected feedpoint resistance of 36 ohms, and an assumption that the ground losses were 15 ohms or less. So at the worst case, the VSWR was near 1:1. The best case, with a ground loss approaching 0 ohms, would have a VSWR of 50/36= 1.39:1.

I want to attribute the original discussion to W2DU, but I stop short of that, in case I don't remember correctly.

Hi Dirk,

Great. We've been fog bound.

I recently bought a $40 SWL radio, and its noise comes from the
display with about 3 MHz bandwidth around the 49M band. I will soon
pop it open for some corrective surgery.

>I have also done the following experiment: Instead of the commercial

Not really - it may cast the problem into a different coupling
mechanism. You still have capacitive coupling and you want to ground
the smallest signal end (the antenna), not the load end (the
receiver).

However, it sounds like it didn't make a substantial difference, or
any difference (seeing as you would have mentioned performance). This
suggests you have driven out as much noise as you can. Anything else
is coming in through the air from afar.

I've read (and tried) all the "expert" SWLing opinions of what pass
for BalUns (even professionals rarely get it right) and experience
still shows a tuner performs better - unless, of course, you really
have a sloppy installation (no choking, poor grounds, poor balance,
running lines past noise sources, the usual stuff).

Hi Wayne,

This strategy may also have you stop adding radials too early when
your antenna presented 36 Ohms looking into a ground loss of 33 Ohms
(same SWR of 1.39).

A set of 120 buried radials each at least 1/4-wave long (free space value) will produce an r-f ground resistance of around 2 ohms, maybe less in soil with very good conductivity.

But in any case the impedance existing between the base of a series-fed vertical monopole and the common point of the buried radials will depend on the electrical height of the monopole which includes the ratio of its height to its width, as well as the r-f resistance in the ground system itself.

Broadcast stations will install the tower and radials, measure the Z from the tower base to the radials, and transform whatever that value is to 50 +j0 ohms using a network at the base of the tower.

Fewer radials will mean that the ground loss will increase, and system radiation efficiency will decrease (even if the VSWR is 1:1)

There is indeed a lot of confusing stuff about baluns circulating in
magazines and on the internet. Is thought it was only possible to use a
antenna tuner at the receiver end when the antenna wire is directly
connected to the tuner, (that is: without using a coax line)
Right or wrong?

What do you do when the antenna wire is not located
at the antenna tuner? Use a transmission line to
achieve maximum power transfer from the antenna to
the receiver (and vice versa for transmitting).
That's the basic function of transmission lines -
transfer the maximum amount of power from one point
to another with the least amount of losses.

Any reasonable transmission line impedance can be
brought to resonance through the use of stubs. An
antenna tuner performs that same maximum available
power transfer matching function.

Hi Dirk,

But you lifted the secondary ground and use the ground at the receiver end (if I understand your description). This creates a capacitive link into the front end through that long path. By the designation of UnUn, both sides (Pri/Sec) of the transformer go to ground. For low noise, this grounding should be at the antenna end of the transmission line (which re-introduces the possibility of ground loops if the receiver is also grounded). You also lose choking action (an UnUn or BalUn does not necessarily choke common mode currents).

>> However, it sounds like it didn't make a substantial difference, or
>> any difference (seeing as you would have mentioned performance).

Then, as the song from Oklahoma suggests, "you've gone about as far as you can go."

A simple test is to tune off frequency to background noise (absolutely no signals). Remove the antenna, what happened to the noise level?

>There is indeed a lot of confusing stuff about baluns circulating in
>magazines and on the internet. Is thought it was only possible to use a
>antenna tuner at the receiver end when the antenna wire is directly
>connected to the tuner, (that is: without using a coax line)
>Right or wrong?

Yes (for the simple answer).

Depends (for the complex answer).

It is far easier to try and see. The issue is one of mismatch and fully coupling ALL of the available power in the signal into your front end. You want a transmission line instead of a drop wire so that you cut down on QRM from devices in the home near you. Hence the

choking of the line to cut down on nearby home noise that conducts/inducts onto the exterior of the shield traveling down to the antenna connection and coming back into the front-end. If you float that far end at the antenna, the noise will simply leap the choke and capacitively couple to the antenna and then travel back into the front end with your desired signal (what a bitch).

The conventional usage of BalUns or UnUns for SWL is for matching, not noise control. However, through careful selection of those BalUns and UnUns by their construction methods, you can get both. Unfortunately, most SWL BalUn UnUn designs are built backwards with the thought that the typical home SWL antenna represents a Hi-Z transmission line with respect to earth. By and large that is true, but as a signal source, most home SWL antennas are Low-Res, Hi-Imp sources. Yes, a Hi-Z results, but it is the R that counts and the step-down is discarding power.

I am well aware that testimonials abound to "prove" nothing is lost. I am equally aware that there are negative testimonials too. As such, this contradiction gives the lie to the credited theory of "magnetic baluns" (the term being a dead giveaway to a con job). I've also read the apology that SWLers don't have time to tune up with every frequency change - sounds like whining slackers to me. Tuners come with knobs and numbered scales. It takes very little effort to log settings once for a band, and use them forever after with slight adjustments to pull in DX.

Power matching involves equalizing the source R to the load R and eliminating the source/load I through conjugation. This requires a tuner which supplies the necessary L for the excess C, or versa-vice (it is, of course, more complex that this, but this convenient short hand is sufficient to explore the topic).

Just to cover all bases, there will be problem tunes for certain frequency/line-length/antenna-length combinations. There is no universal fix. You can anticipate this by building a fan antenna, or using cage construction techniques. Something tells me that this is probably not an option or even within the scope of your interest.

I've found that leading questions, no matter how
ignorant-sounding, are a good learning tool for
everyone, including me. :-)

Example question to someone on eHam.net who says:
"All you need is a 4:1 balun placed outside the shack
at the end of the balanced line to convert to coax."

Where are you going to find a 200 ohm impedance to
match that 4:1 balun that you are recommending for
use in your non-resonant system?

Right. I guess the better way to state it is to stop adding radials when
the r component stops dropping. I've always wanted to try that experiment,
but real estate considerations have prevented it.

With no system to tune the 200 (+/-) antenna to resonance--only at a relatively few frequencies on the dial--unless the antenna, itself, was only constructed for use on a relatively narrow band (or, perhaps harmonically related narrow bands) ... sounds to me, some system of causing resonance was implied?

However, and perhaps contrary to logic, I have seen 4:1 (2:1 to 9:1 for that matter--and certainly "choke baluns") baluns cause a general gain in general performance--and do this more often than not.

Forced to report just what my "eyes" have seen--I, "ignorantly", must state--go figure ... but then again, if it walks like a duck ...

Hi Jerry.

I did not catch the DC part when I looked at the page.

You can always e-mail them and ask, they are pretty quick about returning
e-mails (unless they are at a ham fest somewhere) and they ship fast.

Hi Merlin

I am mainly interested in expanding my understanding of antennas and terminology. My first thought was that there is a way of measuring power that I didnt know about, but everyone else does understand. Since you arent familiar with the meaning of DC when associated with 144 MHz antenna power handling, I am comfortable not knowing either.

Thanks
Jerry

Jerry:

When dealing with xmitters and antennas, it is good to know about ac
watt meters--and, specifically, know enough to get one
responsive/accurate to the frequencies you have in interest.

DC has little to do with xmitters, and, even those of VLF capabilities
... but then, you should get others opinions.

P.S. Beware the "cardboard gurus!"

Dirk I suspect the feed point impedance of your antenna is less than 1 ohm
at 518Khz. This make a good ground imperative. With just a couple of ground
rods for a ground I suspect your ground impedance is probably around 20 ohms
for 60hz and considerably higher for RF. Putting in 120 radials 1/4wl long
would be a tall order but perhaps you could add 20 or so as long as you can.

The noise level drops when the antenna is disconnected from the
receiver. (I'm using a Lowe HF-225 btw)

This is how the receiver sounds:
<http://users.pandora.be/dirk.claessens2/div/LoweHF225BGNoise.wav>

With the antenna connected, tuned on 518 KHz, no signal, it sounds like
this:
<http://users.pandora.be/dirk.claessens2/div/antenna_noise.wav>

Note that recordings were taken during daytime. At night, more static
is present usually.

I guess I have an old antenna tuner lying around somewhere on the
attic. I'm unsure if it will go as low as 518KHz. I'll have to check...

73's and thanks for the many tips - Dirk

1800. Chokes and QRN

I am getting ready to place a choke at the feedpoint of my half sloper, hoping to lower the noise level.

Question: would the same action help with a normal beam (a 3-element SteppIR, in this case)? I think there is a balun of some type in the driven element of the SteppIR, and I do not know how much this rejects noise pickup on the external shield of the coax. (The coaxes for both antennas run about 50' underground, and then about 60' up the tower.)

Hello Owen,

Sorry I am just now getting back to you on this, but I have been reading and studying your article. I constructed a loop somewhat like the one you discuss, but have one question: you speak of a "feed tee" from which the feedline extends. Should I be able to buy such a T-shaped device at my local parts outlet? I asked about such there one time, and was practically laughed at. But it seems such would be very handy for antenna builders of all types. If my local parts distributer doesn't have this item, where can I get it and what should I call it ("feed tee"?)

The loop I constructed is extremely primitive, but still functions nearly as well as the 110' longwire antenna I have used for years. And it is *directional*, though sometimes noisy (probably because the feedline does *not* exit and travel symmetrically away from the loop, I am guessing.)

The main way in which my loop differs from your design (other than the feedline asymmetry) is the fact that the shield is not cut away from the center conductor opposite the feed input. Can you tell me what function this feature serves?

Thanks for your help.

Dave

Hi Dave,

It means there's a cognitive slip between you and Owen (and what is generally constructed as a "shielded loop").

The cut-away is the feedpoint of the antenna. The two semicircular sides extending away from it are the dipole arms (or the complete loop, if you prefer), and the join with trailing feedline is just that.

You would do well to more completely describe your differences as an open must exist somewhere in the shield (yes, an irony for what is called a "shielded loop") for it to work as an antenna.

Hey Richard,

Thanks for the quick reply.

When you say that the cutaway is the feedpont of the antenna, does that mean
it is where the received signal enters the antenna? And the feedline is
where it is carried to the receiver?

Many thanks,

Dave

1808. EZNEC - is there an easy way... SWR... ham-bands only?

I've been "playing" with W7EL's EZNEC a lot (it's downright ADDICTIVE!-),
mostly comparing all-band wire antennas I might be able to construct.

I know how to have it calculate SWR for, say, 3.5-29.7 MHz, but that
results in a really-dense and hard-to-see chart. Is there a way to
have EZNEC calculate SWR for JUST certain hambands withOUT showing
the non-ham-band parts of the spectrum.

For example, 3.5-4 AND 7-7.3 AND 14.0-14.35 AND ...
but NOT including 4-7 OR 7.3-14 OR 14.35-21 OR ....

Hi Myron

You've made me curious. Why do you not want to make as many VSWR charts
as you have "Bands" of interest?
You surely realize that you can record the VSWR curve of each band
individually then save them on all on one page somewhere in your computer.

I have learned things about antennas by recording (on one document) many
radiation patterns with the antenna height above ground changing slightly
between plots. When I scroll thru the plots it almost looks like a moving
picture.

I sure agree with you about the fun you can have with that EZNEC.

Dave, the 'feed tee' I refer to is the tee at the bottom of Fig 1. It is not a standard component that you would buy off the shelf. I have used it as a descriptive term, sorry if it has confused you. The important detail is the electrical detail. In commercial loop constructions, the thing is usually a box, the the loop coax enters opposite sides of the box with effective circumfrential shielding. The box is a convenient mounting and good location for an amplifier if used.

>
> The loop I constructed is extremely primitive, but still functions

> feedline does *not* exit and travel symmetrically away from the loop,
> I am guessing.)

I am not suggesting that loops aren't directional. Shielding a loop is one (and only one of several) of maximising the pattern nulls.

Symmetry helps to ensure that the feedline is not effectively part of the system radiator.

The noise issue may be related to the above.

>
> The main way in which my loop differs from your design (other than the

> the center conductor opposite the feed input. Can you tell me what
> function this feature serves?

I don't understand just what you mean. Perhaps your construction is like Fig 3 (from the ARRL Antenna Handbook), but as stated, it doesn't do what

they say it does. That is not to say it doesn't 'work', or that it isn't directional. The stuff about shielding against electric and not magnetic fields is a flawed explanation.

The real radiator is the outside of the outer conductor, the feedpoint is the gap, and the construction is a clever way of achieving maximum symmetry by placing the feedpoint at the top and routing the coax to the feedpoint in a way that is symmetrical with respect to the outside of the outer conductor of the loop. If you don't route the coax away from the tee in a very symmetrical way, don't waste your time on the complicated construction.

Owen

Hi Dave,

The single turn, shorted loop with an open shield is merely a
convenient construction. It brings nothing new to the table of RF.

Owen's page pretty much describes it all, but there's always the
off-chance it needs to be said again.

The gap is the feedpoint driving your transmission line.

The gap and driveline drop must be at the points shown for symmetry to
insure balance.

Shielding does nothing but describe a balance. You can as easily
remove the shield and obtain identical performance IF you guarantee
balance. This was done for decades before coaxial cable was common.

The gap, the short, and the shield all lend the aura of "magic" to an
otherwise conventional loop. Being "magic" gives rise to ridiculous
claims applied to it. Being "magic" divorces logic from the design.
That loss of logic begins to migrate among the "magic" crowd such that
they come up with useless antennas.

Hi Mike,

RF in the cab will keep you awake during long night drives. Just sit
on the mike enough that if you start to nod off, it fires up the rig
and the seat of your pants both.

Seriously, asking this one question only opens Pandora's box to all
the ways RF leakage and common mode can stop you dead in the road
(blame modern automotive technology). Your mini SUV is the major
radiator, the "antenna" is merely a tuned radial. There are some
elements of a Faraday cage here, but there are also elements of where
the cage fails, so does your control of RF in the cab, under the hood,
in the glove box, what-have-you.

Hi Richard,

For Dave's benefit, I might explain that the risk attendent in using a small loop on a long transmission line is that the outside of the transmission line becomes a significant radiator. In the limit, the loop becomes just a means of exciting the outside of the transmission line as the main element of the antenna system.

That is often undesirable because it spoils the pattern and / or results in pickup of undesirable signals, especially from sources close to the transmission line that has become the antenna.

There are other methods of trying to isolate the transmission line (as Richard noted), the shielded loop construction is not the only way. For example, a BALUN is a device that is designed to permit transition from an balance device (the loop) to an unbalanced device (a coaxial transmission line).

The shielded loop is widely used for instrumentation purposes, where the Antenna Factor (related to gain) is calibrated and needs to be independent of feedline length and routing (within reason).

Hello Bill,

Assuming a good balun, feeder in symmetry plane of beam and the 50"
under ground, I do not expect much off it.

Also when there would be noise climbing up the feeder (to the beam),
the noise could also use the (metal) mast.

You might place a signal source at your location close the coaxial
feeder. Add some common mode rejection and see whether it works. You
should source ferrite material with the highest impedance at the
working frequency.

Best regards,

Wim

> I want to attribute the original discussion to W2DU, but I stop short of
> that, in case I don't remember correctly.

I think it would be a lot MORE interesting to follow the change in
impedance as you add wires. I can see a lot that can go wrong with
"adding radials till the SWR stops increasing." I don't think that
the case of 33 ohms ground resistance is one to seriously consider*,
but if you're operating over really poor ground and/or your "quarter
wave" antenna isn't really a quarter electrical wave, you may see
significant reactive component that you'll never resolve with an SWR
meter. You'll likely get very confused by it instead.

*What's the "ground resistance" with as few as two radials, even if there's no earth ground nearby? What if there are no radials but the ground is really awful? Some "what-ifs" with EZNEC or the like can give you an appreciation for what happens...

Cheers,
Tom

All I can tell you is,

I bought one for my truck connected to a yaesu ft-2800m, 65 watts.

Me and another ham were supporting a bike ride and were posted at a fire station, out in the middle of nowhere.The other ham had his rig and a j-pole that he ran up the fire stations flag pole..25feet high or so.
We ended up using my rig. Much better performance over all.In a steak hole mount in the bed of my truck.
I liked the antenna so much that I use another one for my base station.
It will take massive abuse, tree limbs at 60mph on the whip part of the antenna etc.

It will run all of the 2 meter band with very little loss.

I do however like antennas that use a lot of wire, the more wire in the sky, the more area you have to pull in those weak signals. that is as long as it is done right and lakeview has got this one right!!

I have no interest or personal gain by posting this, I just know a good product after I have used it for several years in the field and used it in the worst conditions possible. AKA 2 days after hurricane Katrina in Mississippi and trust me that antenna hit many a tree branch and a few other things on my trips thru hurricane damaged areas.

Sorry, (I got on a rant)

Hey Owen,

I am unclear on the use of the term "feedpoint" to describe the exposed center conductor of the coax. Can you give me a little more detail as to what this means? Sorry, I just don't understand why it is called the feedpoint. I somehow thought that was where the coax connecting the antenna to the receiver/transmitter was attached. And just for the record, I am only going to be receiving with whatever type of loop I end up with. What I am actually seeking is a small loop that I can attach to my tunable RF amplifier for feeding enhanced signal to my Sony 7600GR shortwave radio, making a portable unit to pair with the radio, allowing me to set them both up wherever I wish.

Oh, and the primitive loop I currently have is a piece of coax forming an (approx) 18" loop, with the center conductor connected to the outer shield and none of the shield cut away.

Thanks again for your help...

Dave

Mike,

I'm sure there are a lot of opinions but here is what I do. Assuming your mobile antenna is pretty well matched and you are running 100W then the differential current in the coax will be about 1.4A. I have an industrial clamp-on current probe that connects to a small battery powered RF power meter (you can use something else) and I would measure the common mode current on the shield of the coax. If the common mode current was greater than 10% of the differential current in the coax (0.14A) on any band of interest then I would use a good quality 1:1 balun. Why 10%? I have no real reason but I have done many mobile installations and have nearly 30K mobile qso's and have no equipment interactions or problems.

Obviously if the common mode current is minuscule then there no value in having a balun. Also using a balun will do no harm and only cost you a fraction of a dB. in loss.

73,
Larry, W0QE

I have used the term feedpoint to denote the point that delimits the role
of the transmission line and the radiator.

> just for the record, I am only going to be receiving with whatever
> type of loop I end up with. What I am actually seeking is a small

Ok, but broady speaking, the effects that apply to considering the antenna
with a tranmsmitter also apply to using it as a receiver.

If you want to think in receive terms, your coax feed line may have RF
currents induced on the outside of it from local and distant sources, and
if at the tee at the bottom of the loop, that current divides equally into
both halves of the loop, it will not result in a voltage difference at the
gap. The current will only divide to equally if each side of the loop is
symmetrical to the feed line and everything else near to it.

Again, I think you are describing the loop shown in Fig 3 of my article. You don't need to use coax for the loop itself, it is not a balanced loop as described and coax doesn't help with balance. If it was you intention that the loop was not susceptible to pickup on the feedline, the antenna you describe does nothing to prevent that. The shielding explanation for that type of loop is bunk.

Owen

Okay, well, all I am trying to do is build something that will pick up weak signals from a given direction, while ignoring signals and noise from other directions. Ideally, it would not introduce a great deal of noise from any source (unlike the loop I currently am experimenting with.) I am not overly enamored of complex designs, and don't really care what it looks like so long as it meets the above criteria. Do you know of any fairly simple designs that would meet this description? If tuning is possible, that would be a plus.

Thanks,

Dave

I suppose that I could try with and without,and just find out.
There is at least one 2 meter Frequency that kicks me out of overdrive.
Fortunately it is on a repeater that I only use when out of town.

For your MW RO application, I would look at a multi turn (unshielded)
loop, untuned or tuned, but with an effective balun isolating the outer
surface of the outer conductor of the coax feed line from the loop.

I responded originally to your question about shielded loops. Shielding
is only one way to improve loop balance, and most explanations of
shielded loops are flawed.

Google for some designs, and be suspicious of purported shielded loops.

BTW, loops have pattern symmetry about the plane of the loop, so they
don't favour signals from only one direction. Think of them more as
having two diametrically opposed narrow reject regions in the patter, the
two accept regions are much broader. If you want maximum rejection,
balance the loop wrt the feed line and everything else near it.

Source record: 35909

Hi Larry

Just a quick thought.

Since a moved from the marine band to 2m is down in freq you may get away with something you can slip over the marine whip to increase C to ground. I am thinking something loose here, not so much a metal to metal connection. Since there will be a greater effect at the top end maybe a piece of metal pipe just sitting close to the top, maybe buffered with a grommet or something to hold it in place.

Might be worth an experimenting if the 2m VSWR on the marine whip is beyond bounds!

Of course if you have the money to throw at it, mounting a high gain vertical on a steadicam mount might solve the movement induced pattern problems! <grin>

Cheers Bob VK2YQA

One thing about small loops.. They are great at nulling ground wave
signals,
but not so great at nulling skywave signals.
So how well a small loop would work will depend on the source of the
noise.
If the source is local, IE: a noisy power line, etc, that signal will
arrive via
a space or ground wave, and you can null that noise very well.
But if the interference is via sky wave, you might get a reduction in
strength,
but usually not a total null.
As a general rule, small loops are best suited to the lower
frequencies.
They work ok for the HF bands, but you may not the see all the
benefits
on those bands that you might on the MW bands. But even one used
for HF should get a decent null on a noise signal as long as the
source
is fairly local.

As far as shielded loops, I've carefully compared both unshielded and shielded loops, and couldn't really tell a lick of difference as long as
both are balanced. I've also tried using unshielded loops, but with a shielded coupling loop. Again, no difference, as mine are fairly well balanced even using a regular unshielded solenoid loop.
I had just as deep nulls unshielded, as I did shielded.. No difference in perceived noise either. So I consider using shielded loops an option,
but usually not needed. As many have mentioned , the only advantage is to help ensure balance, and in most cases, it's not a problem to worry about.
I do mount everything very symmetrically though. I make mine with very simple PVC frames.
IE: one example... http://web.wt.net/~nm5k/loop5.jpg
But my big one is even more simple. Just a thick appx 2-3 inch PVC "mast", and regular 3/4 inch PVC for a cross arm, using PVC "Tees" at the ends to thread the wires through.
The 3/4 inch PVC crossarm is run through drilled holes in the larger PVC
mast. I drill them to fit tight, and I don't even have to glue them, although
thats an option. I use stands to mount the loops on, and they can be easily turned.

I might be able to shed a little more light on this.

If you directly feed an unshielded loop, you cut a gap in the loop and connect a transmission line across it. Current induced in the loop by a signal flows from the loop to the transmission line via this connection.

In a "shielded" loop, the signal induces a current on the outside of the "shield". At the gap, the current flows to the inside of the "shield" where it induces an equal and opposite current into the inner loop itself. The inside of the "shield" and the inner loop comprise an ordinary non-radiating coaxial transmission line, so it can be said that the gap is where the signal-induced current enters the transmission line, just like the gap in the unshielded loop. And so the gap in the "shielded" loop is a feedpoint in exactly the same sense as the gap in an unshielded loop.

Hi Mike,

The cabin of a car or truck makes a fairly poor Faraday Shield to 2M.
Try as you might to correct things through a choke (conduction), there
may still be problems (radiation).

It is at this point that most vehicle owners discover all those parts
of their vehicle that are NOT grounded (or, rather, continuously
shielded). Hoods are usually floating with respect to the chassis and
make a great capacitor to the interior of the engine compartment.
Exhaust systems similarly float and are sometimes resonant in upper
HF. Doors hinge on plastic bushings... and the list continues.

Good point and that is why I am a little confused about using chokes to
lower noise --- in any situation where the coax goes up a tower.

A number of very well-written and interesting papers
describe the effective rejection of chokes (over 5000 ohms when looping the
coax
through several #31 toroids), but they do not discuss the effects on the
total antenna system. As you said, it would seem that any pickup by the coax
external shield would be mostly duplicated by the tower itself and this
would bypass the choke if the coax shield is "grounded" to the tower at the
feed point. (Yes, I know "ground" has many meanings.)

I can see where the choke would help with a dipole, where the coax is not
connected to the tower at all.

Hi Bob,

Well, after a bit of experimenting (and remember I'm almost always on an inland lake) I decided to go with the Morad antenna. I've ordered one and a mount - it will probably be here next week. I'm not too concerned with pitch and yaw - it will be close enough to vertical!

Yes, I could detune a marine band antenna - for that matter, the SWR is probably close enough, but this should work and there's some genuine gain, but not so much I have to worry about keeping it vertical.

Actually, I'm lazy!

I have read about the need to use some copper braid to ground a lot of
the parts on the car. The exhaust system is certainly around the length
of the antenna mast in itself.

Hi Bill,

The confusion may arrise from the tower's two uses. For the sloper,
it is active; for the beam it shouldn't be.

For the sloper, choke the line at the bottom of the tower. For the
beam, choke the line at the top and the bottom of the tower.

However, as far as this conventional advice goes, the lower choking
would seem to be redundant to the 50 foot run under ground. That
should choke the line just as well. If the beam comes with a choke
(I'm not sure how much they invest in that technically instead of just
for advertising's sake) then there's no point in more there either.

Take a clamp-on ferrite, build a loop of a dozen turns of fine wire
through it; terminate the wire with an LED. Attach this inside the
shack to any feed line and see if the LED lights up during a QSO. If
it does, you may want to replace the LED with a RF Current meter to
see just how much current there is, but my guess is the LED will be
dim at best. [LED current of 10-20 mA @ 2V will be quite bright.]

One of the first things I learned in my RF education is that a
gap does not necessarily stop the flow of RF, and neither does
a short! The mysteries of shielding I am still learning about.

I thought I had it all nicely sorted out, and then along came
the Fractal antenna! :-)

1843. Car radio antenna has an inline .85mfd capacitor, why?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-29 00:16:30 UTC
From: Bill Freeman <nobody@nowhere.invalid>
Message-ID: <280920072016306378%nobody@nowhere.invalid>
Source record: 35923

I have an 87 Nissan van with an antenna wire that has a 0.85 mfd capacitor soldered between the center wire and the center pin of the antenna connector, on the end that plugs into the radio.

This vehicle actually has two antenna wires that connect side by side at the radio. One antenna is printed onto the centerline of the windshield, and the other is a conventional whip antenna mounted at the drivers side of the roof. The roof antenna lead is the one with the capacitor.

Anyone know what the purpose of an inline capacitor would be on a car radio?

Another car antenna question, why do they use such a small diameter wire inside the coax? The wire inside this coax is about .010 inches in diameter. Is it this small to save on copper, or is there some technical advantage to a small diameter wire.

That seems a very practical ap note. But since you issued the
challenge, I'll say I disagree with the wording of an early sentence,
where it says that ground return currents are "greatly attenuated" if
they come through lossy earth. Clearly, the current is not
attenuated; the current is what it is. However, the current through
lossy ground causes power dissipation (and loss of radiated power) in
the ground.

I think the meaning is clear, but the wording would not pass muster
with a good technical editor.

Cheers,
Tom

Hi Bill,

Probably for DC isolation (yes, what DC? is reasonable to ask, but it
is probably cheap insurance against an accidental short from antenna
to ground taking out the front end bias, or from static build up (but
a good choke to ground would solve that too)).

>Another car antenna question, why do they use such a small diameter
>wire inside the coax?

To reduce parallel capacitance to ground (line Z is rather immaterial
but its equivalent capacitance is not).

Good catch. It could have been more precisely stated.
In defense of the the point, Dictionary.com offers this definition of
"attenuated"- to weaken or reduce in force, intensity, effect,
quantity, or value.

OTH, lossy earth is a limiting factor to the current component of the
equation.

I think it unlikely to be misinterpretd so I would be inclined to
leave it alone. Of course, I am not a Technical Editor.

But without a low-loss r-f ground for a monopole such as provided by a good buried radial system, those returning r-f currents ARE greatly attenuated before they can enter into the ground terminal of the antenna system.

That ground resistance is in series with the radiation resistance of the monopole, and so will reduce the current that will flow on the monopole -- hence the field it will radiate.

Below is a link to a calculator on the FCC website giving some insight into this. It restricts inputs to values allowed for AM broadcast stations, but still might be of some value to amateurs.

For one example, it shows a 1/4-wave monopole using 120 x 1/4-wave buried radials as generating a groundwave field of about 306 mV/m at 1 km for 1 kW of applied power.

If the number of radials is reduced to 90, and their length is reduced to 0.153 wavelength, the groundwave field is reduced to 267 mV/m.

The difference in radiated power then is (267/306)^2, or about 24%, which value is dissipated by heating the earth.

Whether or not that reduction is important to amateurs is a judgment call. But an antenna system producing 267 mV/m for these conditions would be unusable by a "regional" AM broadcast station -- which per their station license must produce a groundwave rms field of at least 282 mV/m at 1 km for 1 kW of applied power.

> attenuated; the current is what it is.

There is some confusion between DC circuits and
distributed RF networks. In a DC circuit, the
current is the same throughout the circuit. In
a distributed RF network, the current is usually
NOT the same throughout the network. One can
put one amp of current into a buried radial and
measure zero amps from some point outward.

In particular, when dealing with RF EM waves, the
H-field to which the current is proportional in
a transmission line is attenuated by the same
attenuation factor as is the E-field to which
the voltage is proportional. Please reference
the transmission line equations to verify that
fact.

Such is easy to see. If one has a flat Z0=50 ohm
transmission line with 100 watts in and 50 watts
out, there is 1.414 amps in and 1.0 amp out because
the ratio of voltage to current is fixed at 50 ohms.
The traveling-wave current in an EM wave in a
transmission line (or in a radial in lossy earth)
is attenuated exactly as much as the voltage.

And don't feel too ignorant about that fact of physics.
Some of the gurus on this newsgroup make a similiar
mistake about RF EM wave current through a loading coil.

Richard, too many people, including some of the gurus,
are thinking DC circuits. The only difference between
the voltage equation and the current equation is a
division by Z0, i.e. the current is attenuated exactly
by the same factor as the voltage.

This is a good example of why we shouldn't assume that what's suitable or optimum for AM broadcasting or some other service is necessarily the best solution for amateur applications. A reduction in radiated power of 24% is just about 1 dB. While this amount of attenuation makes the system unsuitable for AM broadcasting, it would be difficult to even detect that amount of difference except just perhaps in the most demanding amateur communication -- right at the noise level -- and it would go completely unnoticed in the vast majority of cases.

From: Bob Bob <bob3bob3@suddenlink.net>
Message-ID: <ph33t4-uk1.ln1@p400bob.personal.cox.net>
Source record: 35938

Hi all

I am gradually working up to a project to TX telemetry from the car at very low QRSS type data rates. Because of the unattended nature of the system I am going to start using the HiFER freq of 13.56Mhz rather than a "real" amateur allocation.

This of course means very low output power and no doubt a number of other limitations for the TX. I really only need the system to work predominately <10 miles from the base.

Yes I am aware of the frequency stability issues for very narrow band signals. No doubt the vehicle bouncing around wont help either! May end up using a Picollo type system where the freq difference between two states is used to send data.

I am after some feedback and ideas about antenna systems to use. I suspect the car TX antenna will only be a wire draped across the rear window or a loaded broadcast antenna. The RX base antenna was going to be just a dipole but I reasoned that this would be great for DX but terrible for groundwave. Then thought about a vertical dipole, but am concerned about the higher noise level. I'll probably end up trying both. Initial tests are only going to be looking for a CW signal on a waterfall.

Would also consider experimenting at a MedFER freq around 1700KHz but base antenna efficiency might be pretty bad. There is also a lot more RFI there.

Ideas welcome. If however you want to say it "wont work" please back it up with some maths/calcs or your own direct experiences.

Cheers

here in the states we call 13.56MHz an ISM frequency. Meaning Industrial, Scientific, and Medical. near any populated area you are liable to run into diathermy machines, plasma ovens, rfid tag readers, and a host of other noise generators there. i would suspect your environment may be similar.

for ground wave the vertical would probably be best, especially for omnidirectional covereage... though a low dipole would likely work almost as well.

frequency stability with modern equipment shouldn't be a problem, just be sure to build everything nice an solid so it doesn't 'bounce around' and it shouldn't be a problem... not like bouncing around tubes with mechanical elements that would vibrate and move in the distant past.

Of all the HF antennas one might reasonably make out of wire or
aluminum tubing, which produces the strongest groundwave?
Ground-mounted quarter-wave vertical? Horizontal dipole at a height of
1/4 wavelength? Or what? I'm sure someone must have experimented, or
done computer modelling, to seek an answer to this question but I am
not finding any information.

If all things are set up properly, normally the 5/8 will give the
strongest
ground wave for a single element. You have very little if any true
ground
wave from a horizontal antenna. You do have a space wave, but it's
not
quite the same.

That would explain something I experienced years ago. A DF loop mounted thru the roof on a metal building worked great, when it was moved to another building with fiberglass roof and walls its performance was degraded to the point of being useless for our purpose.

I am able to work 40 to 45 miles from my mobile, using a 20m Hamstick in the center of the sedan roof, to a friend who is using a ground mounted vertical made from half a driven element from an old tribander. We are both running 100W SSB, and the received signal levels are just enough above the noise level to communicate. The terrain is relatively level, and the path is from the western Minneapolis suburbs to a town southwest of Minneapolis.

Hello "Anonymus".

I assume that you want to maximize field strength close to ground.
At the low HF (and of course medium wave), the surface wave
contributes lots to the signal strength. These ones you can only
excite with a vertical polarized antenna. Also elevated vertical
antennas induce surface waves, so a ground connection is not mandatory
(but many times required practically because of antenna size).

As mentioned by other poster, 5/8lambda vertical fed over a good
ground network gives highest gain in horizontal plane (with a minor
side lobe).

At high frequency (and low ground conductivity), surface waves do not
play an important role. In that case height is the determining factor
(with high directivity in the horizontal plane). Polarization is of
less importance.

Best regards,

Wim

Good advice about the sloper; and about the 50' underground acting as a choke. I was hoping for a magic solution to a little of the "atmospheric" noise on 80 and 160, but there may not be any magic.

I do not sense much of a noise problem with the beam, but I will try a choke at the feed point sometime. (The coax to the beam also has the 50' underground run, so a choke at the bottom of the tower is probably not needed.)

Hi Bill,

The reason why you would choke or beef up an existing choke for the
beam is as to deepen the nulls that are filled by the 60 foot drop
line that might be radiating/receiving. In a sense, this choking
would lower noise coming in from what should be nulled regions in your
pattern.

Many thanks Tom

I can probably extrapolate from those numbers.

I haven't looked at the ISM/HiFER rules/regs but the QRSS type mode
itself is going to be maybe 20-30dB "better" than SSB. I guess I'd be on
par with your numbers at 100-200mW o/p
Cheers Bob

1875. Re: Speedup NEC-Engine, using multiple CPU-Cores

Newsgroup: rec.radio.amateur.antenna
Date: 2007-09-30 22:35:46 UTC
From: oeguet@gmx.de
Message-ID: <1191191746.003756.117680@19g2000hsx.googlegroups.com>
Source record: 36005

Good news!

It is really possible, to speed up NEC calculations with CPUs containing more then one core. I will try to implement a wrapper-executable, that makes possible with your old NEC-engines (e.g. NEC2). It need no recompilation of nec engine or any modifications. Just renaming the old engine and putting the wrapper-engine on the same directory with the original nec engine file name.

After implementing a new antenna optimizer (that one uses also multi-core, multi-cpu enhancement), I will start with the wrapper code. I will test the code with 4nec2, so many of you could take advantage of multi-cores with 4nec2.

regards,
Aziz

1876. Re: what homebrew HF antenna produces the most groundwave?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-01 00:40:21 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <13g0gfknu9nhbcf@corp.supernews.com>
Source record: 36006

Wim mentioned the high angle lobe you get with a 5/8 wave antenna. It produces a sky wave which can, if skip conditions are present, interfere with the ground wave signal and cause fading. This could be a very common and serious problem at higher frequencies where the ground wave is weaker and the sky wave stronger. You can reduce this by keeping the radiator height to 1/2 wavelength or less. Antennas in that height range don't have a high angle lobe, although they do produce some radiation at high angles. Radiators near a half wavelength in height produce less high angle radiation than shorter antennas, and they have more horizontal gain, so I'd think they would be best. I'm sure the AM broadcasters have other "anti-fading" techniques -- other newsgroup contributors would know much more about them than I do.

In my truck I had a Motorola 800 MHz ConvertaCom unit that worked with a XTS5000.
The ConvertaCom has been removed, but the Antenna, NMO antenna mount and the Coax cable have not been removed.
I would like to put in a scanner and use the 800 MHz cable by putting an adapter connector on the inside end.

Can anyone tell me what the end connector on the ConvertaCom cable is?
Where can I get an RCA or PL259 adapter?

Hmmm.. Isn't that the version that used f2c to convert the FORTRAN to C? Probably a bad plan overall.. there's some reputed bugs in the process, and it's going to use different libraries, etc. If you're worried about performance, stick with the FORTRAN and use a good compiler.

An excellent idea. Arie has already put a decent symbol substitution
processor in, so if you can read the same files, and then farm out the
various symbol values to the processors in a reasonable way, that
would be pretty useful.

1880. I have never heard of installing a tower this way...

Newsgroup: rec.radio.amateur.antenna

Source record: 36010

I went to visit a ham acquaintance of mine today. He is putting up a 100-foot tower with a large HF beam on top, guyed in three places.

He is not fastening the base plate of the tower to the concrete base in any way... the tower just rests on the top of the concrete base, and the three sets of guys hold it in place.

He explained that the main failure mode for towers is due to twisting in high winds with high-wind-load antennas, so by not fastening the base plate in any way and just letting it rest on the concrete, he allows it to rotate a few degrees if needed (by sliding on the concrete) and lessens or prevents rotational stress on the tower.

I understand what he is saying but this is the first time in 45 years as a ham that I've ever heard of a tower being erected in this way.

Is this a common way to install a tower, and does it make sense?

Sure does seem to me like bolting the tower base plate down to the concrete has a lot more upside than downside, but WDIK?

Reminds me of a day back in the 1970's when a bunch of us were working on a 120-foot tower, guyed in three places, that held our repeater antenna. Due to events the details of which I have long since forgotten, all three of the guys on one leg became disconnected so that there was absolutely NO guying support on that side. One of the team was about 80 feet up the tower at the time. The tower curved over like a banana but stayed up, and we were able to re-install the guys before the tower came crashing down taking our friend with it. He did have to change his pants, though. :-\

Pretty easy to imagine what would have happened if the tower base hadn't been fastened down...

Source record: 36012

Hello Jim,

on the last 6 month, I wrote a "C-language-like" NEC-Compiler, which generates symbolic antenna models and therefore the output model can be read directly from 4nec2. The generated code is fully symbolic, so the antenne parameters can be optimized with 4nec2 as usual.

As an experiment of one of the simplest optimization function (monte carlo method), I started the new optimizer and of course in the hope of getting some speed enhancements. Some antenne problems have a big local minima problem and sometimes the optimization get stucks in a next optimum level (local minima), but not the best one (global minima).

With the monte carlo method, this can not be happend, but it takes much more computation time. The new optimizer of course, uses the new NEC-compiler, to generate different parameters and NEC-Input for the engines.

At the moment, I interrupted the development of the optimizer and startet with the NEC-Engine Wrapper. I have coded during last night the most parts of it and I just have to merge the results now. On my dual-core Intel CPU, the performance level of the CPU goes directly to 100% with running two NEC-Engines in the background, so they use all the CPU-Cores at the same time.
Merging the results, is much more non-trivial part. I hope, I can solve this very elegant.
The integration of the NEC-Wrapper will be transparent and seamless.

I will see, how far I can go.

Regards,
Aziz

I forgot to mention, that the nec code is compatible with 4nec2-files.
I am also able to compile the 4nec2 symbolic code. And the compiled
output is also compatible to 4nec2.

1884. j-pole 5/8 wave

Hello all,

As a new Novice amateur I am considering to build my first antenna.
I know that starting with a j-pole is simple and easy. However. I see many plans on the internet.

One of interest is the stacked 5/8 wave j-pole.
I only see this in a stacked version. In a not stacked way I only see the half wave version with a quarter stub.

Can a 5/8 wave length and 1/2 wave stub work as a real 5/8 wave antenna?

Looking forward for any suggestion!

With the weight of the tower and the downward force of the guys aiding
the friction on the base, and the guys' resistance to the tower twisting
I doubt not fastening the base has any appreciable effect, but as you
said (farther down), WDIK?

Even so, It's very doubtful the friction will be the same over the whole
base-concrete interface, such that on a windy day his tower might just
walk off the concrete or at least far enough out from under the rest of
the tower that the force from the guys becomes unbalanced enough that it
pulls itself down, but as has been said, WDIK?

> I understand what he is saying but this is the first time in 45 years as

If it's common it's a well kept secret.

> Sure does seem to me like bolting the tower base plate down to the
> concrete has a lot more upside than downside, but WDIK?

Exactly, what do we know? If he's able to get a licensed, professional
engineer (who would know) to sign off on it I'd come within a radius of
1.5 times the tower height, otherwise I'd keep my distance.

This method sounds very dangerous. I could see putting some kind of
bearing or at least a recess so the base doesn't slide out from under
the rest of the tower but just plunking it down without any method of
keeping it on the concrete, yikes!

Death, destruction, litigation... you should advise Mr. Baseless to
have a licensed engineer look over his installation, especially if
there's any insurance companies involved in any way.

But yeah, WDIK?

The homemade (very crude) 1/2 wave with a 1/4 wave matching section that I described in another article easily made great contacts from Pennsville, NJ (Wilmington, DE) to Philadelphia on simplex with ease. It was even indoors when I did it and I was running 10 watts or less. That is about a 30 mile distance. Mine was constructed of two pieces of #8 aluminum grounding wire stuck into two holes drilled into a piece of 2x4 as a base, sitting on my table a few feet away from my rig inside of the house. That was good enough for me to hold QSO's on FM and sideband with all of my Philadelphia friends (WA3RXE and several others).

A 5/8WL needs inductive reactance to resonate it.
An inductive stub will do that but a 1/2WL stub
will not. FYI, for a 2x5/8WL dipole, a 0.2 WL
series section of 450 ohm ladder-line is a pretty
good match to 50 ohms.

If the base of the tower were in a small pit then it might work, otherwise there is a huge danger that the base will kick out and the whole lot will come down.

Hi All:

I've seen profesonal towers put up that way, sorta. They had a single pin
that a hole in the flat tower base set over. The pressure of the guys keeps
the base on the concret pad and the pin keeps it from kicking out to the
side. With out the pin, it's going to come done sometime.

In a simple way... I have a vertical radiator of 2 x 5/8 wave length. That is serie with 450 ladder line one side connected to the radiated element and the other to a groundplane will work?

Hmmm... Now that you mention it, I recall that the base plate had what looked like a capped tube rising from its center. Maybe that tube goes down over a pin of some kind that was embedded in the concrete.

I'll have to ask him about that.

I cannot tell from your description what is your
exact configuration. Is this it? (fixed font)

```
GndPlane--+ +-------------------------------------
| | 1.25WL vertical monopole
| |
| |
| | 450 ohm ladder-line
| | to transmitter
```

Simple vertical monopoles should not be longer than
5/8WL.

Hi Bryan

If a guy was determined to chase damaged threads rather than replace the
connector, he could cut some slots in a steel nut that has the right
threads. A 5/8-24 nut is probably affordable.

Hi Cecil,

In your first reply you talked about 2x 5/8 wave with 0,2 wave in serie to
50 ohm.
That is the same as in your example here? Or must we use it al the way up to
my transciever? I am still talking about 5/8 wave for 2 meters.

One way to get more ground wave without introducing the high lobes is
to use a collinear vertical. Just how practical this is depends on
the frequency of operation and what you have to hold the antenna up.
For example, on 30MHz, you could pretty reasonably put a half-wave
above a half-wave or above a quarter wave. On 3.5MHz, that would be
much more difficult for most of us. Even on 20 meters, you might be
able to do a collinear vertical. I suppose that MW AM broadcasters
are unlikely to use a vertical collinear, but maybe one of the other
contributors with lots of broadcast antenna experience could comment
on that.

Cheers,
Tom

HI Larry,

As an update, and not specifically about th ebalun issue, I tweaked my system over the weekend.

Noise was an issue. When I first installed the antenna, it was on a fairly quiet day, RF wise. The unmodified Vitara pumped a slew of noise onto the radio. Without the engine running, I was seeing around S3-4 Noise. Turn the ignition on, and we're looking at S-9 worth of noise. Obviously not too cool.

I installed ferrite snap ons onto various lines, such as the alternator, the power lines to the rig, the power to the radiator fan. I then ran wire braid from the hood to ground, and grounded all the doors the same way.

Yesterday afternoon, I tried a test drive of the system. Much much quieter, although I hesitate to say exactly how much, since the band was a lot noisier to begin with.

I still have to ground the exhaust system, and try a ferrite on the fuel pump, which puts a little noise into the system. I still have to find the fuel pump, though. I'm assuming it is on the tank - but I think a call to Suzuki is in order.

40 meter operation was quite successful as far as the antenna working. Good reports all around.

As also expected, there were a few in-vehicle issues.

One minor one is that the oil pressure light turned into a nice little modulation indicator. This was whether the vehicle was running or not. I'll probably put a ferrite on the power line to it in hopes of knocking that out.

The other issue was that my voice would come out of the car stereo speakers. A bit distorted but legible. I'm not sure if this was the signal getting rectified somewhere or what. It would do this regardless of if the stereo was turned on or not- thought oddly, it would start only when the vehicle was turned on, and would go away gradually. At any rate, I'l have to be sure to get that one fixed.

Finally, and this is not noise related, but I put a capacity hat on the antenna as suggested by many. Being a homebrewer, I used what would best be described as a "big freakin' pizza pan", a 16 inch pan mounted upside down.

Turns out that I can adjust quite a bit lower in frequency than I expected, and I will definitely have to shorten something up to run higher than 20 meters.

I used an aluminum tent stake to temporarily stake a radial wire to the ground during some testing I was doing this summer.

After the test, I forgot to take it out of the ground.

Two weeks later I noticed it and reached down to pull it out of the ground. I pulled it out easily and was amazed to see only the top half of the stake in my hand. The thing had corroded almost all the way through right at ground level and the bottom half was still stuck in the ground.

How could it have completely corroded through an aluminum tent stake in just two weeks in my dirt?

No, my first reply was about a 2x5/8WL dipole fed in
the center with 0.2WL of ladder-line and no ground plane.

> Or must we use it al the way up to
> my transciever? I am still talking about 5/8 wave for 2 meters.

You can turn the 2x5/8WL center-fed dipole vertical
in which case, like a vertical center-fed 1/2WL dipole,
it doesn't need a ground plane.

Almost all US AM broadcast stations use non-sectionalized vertical monopoles, but a few use a form of the Franklin antenna comprised of two collinear, end-fed verticals.

The current thought on this in broadcast circles is that the additional h-plane gain that provides over a 195-degree non-sectionalized monopole isn't worth the initial cost and the continuing need to check and adjust the power division and phasing between the sections of a Franklin.

In a nutshell, you either made yourself a crude battery, or you
electroplated the dirt the stake was driven into with a layer of
aluminum. Precisely which one is the reality depends on, among other
things, soil pH, the material of your radial and whether or not your
radial was electrically hot (even if only a little) for whatever reason.
if I were a betting man, I'd put my money on "battery".

(See also "sacrificial anode" under the "boating" category)

Vertical antennas make the strongest groundwaves.

Assuming you are confined to a single ground-mounted element of
reasonable height and complexity, Kraus in the 3rd edition of "Antennas"
gives a simple answer in Figure 16-35 on page 569. A 0.64-wavelength
tall vertical radiator produces the greatest field strength at one mile
in the direction of the horizon.

that would be what's known as a "pier pin" base, and, as noted, it
greatly reduces the torsional load on the tower. Whether the force
causing the tower to fail is torsional, I'm not sure. Guyed towers fail
by buckling from the compressional force exerted by the guys.
Obviously, putting another force on the tower in addition to the
compressive force is going to increase the load on at least some member
of the tower, and if failure of that member causes enough asymmetry to
get the buckle going, then it is an issue.

Hi,

What is the difference between multiple input multiple output (MIMO)
system and
Adaptive antenna system (AAS) ?

I find the WiMAX uses MIMO and AAS . But, the definition appears to be
the same.

Both the systems are exploiting more than one antenna to improve the
coverage and the system capacity.

I wonder why different naming convention for the same system !! :(:(
Is there any significant features/differences in MIMO and AAS ?

Thx in advans,
Karthik Balaguru

Yup. Fairly common in commercial tower installations as I've seen
several. Seems to be unique in ham installations, though.

Some commercial towers mount similar, but the ones I've seen have a
fairly large peg sticking out of the concrete and mates with the tower
base and the guys hold it all in place.

Hi,

I got some info from internet.
There are differences between MIMO and AAS Antenna Technologies:):)

It appears that cost-effectiveness comes in terms of the antenna and
MIMO (Multiple Input, Multiple Output) and AAS (Adaptive Antenna
System) are
competitors.

MIMO delivers the same coverage as AAS

MIMO delivers higher capacity than AAS

MIMO is lower in complexity and cost than AAS

MIMO is more scalable than AAS. MIMO is more predictable in
performance
and can grow through additional sectors and/or additional antennas

MIMO works well in all environments (rural, suburban, urban),
switching modes to deliver users the best experience.

MIMO outperforms AAS for mobile applications: MIMO maintains
performance at speed and provides a predictable environment for easier
and

more reliable hand-offs.

MIMO is the basis for all 4G plans- widespread investment in
developing
MIMO technologies will ensure advantages are maintained.

So, it looks like in all aspects, MIMO is equal to or superior to AAS

No..

MIMO uses the fact that if you have multiple receivers and transmitters at each end of the link, the properties of the paths are uncorrelated to some degree, so you can spread your data across the multiple paths, reducing the bit rate on any one path. One use would be to use some sort of FEC coding, transmitting multiple bits for each data bit to achieve a lower overall bit error rate (after coding/decoding).

AAS is more like adaptive beamforming

In the limit, they are similar.

The vertical elements of a tower framework should take their load in line with the element. They are slender elements which are tied in by bracing to prevent buckling.

It seems to me that in a typical construction where the end of that vertical element in each section is not free to hinge, that twisting of the section deforms the vertical element and would assist buckling if the downwards force in the element is very large... as it is on very large structures.

(If you read the USCG manual on towers, they are obsessed with ensuring that not only is the tower vertical, but that each vertical element is vertical (ie twist within specified limits.)

I wonder about the benefit in shorter structures, but can see that dynamic forces caused by rotator brakes trying to instantly stop a rotating beam might be better accommodated by the pier pin base.

For hints on amateur applications of towers, look at these pics:

(note the extension of the winch handle)

http://www.users.bigpond.com/vk3bjm/gallery_files/image016.jpg

and the counterweight in more detail:

I too found they were rather expensive thats when I remembered my neighbor was a machinist. She wouldnt let me borrow her die but she very kindly rethreaded the connector for free.

Hi Karthik,

Only with the qualification that AAS may be steered to the same points
of coverage of MIMO - and that is not always assured.

>MIMO delivers higher capacity than AAS

What is capacity? There are counter-arguments (depending on
capacity's meaning, there are several) that would invert this claim.

>MIMO is lower in complexity and cost than AAS

An engineering system solution is not always about one component cost.

>MIMO is more scalable than AAS. MIMO is more predictable in
>performance
>and can grow through additional sectors and/or additional antennas

You should study the information and skip the claims you've heard.

>MIMO works well in all environments (rural, suburban, urban),
>switching modes to deliver users the best experience.

This is not an antenna issue.

>MIMO outperforms AAS for mobile applications: MIMO maintains
>performance at speed and provides a predictable environment for easier
>and
>more reliable hand-offs.

If AAS is boresight along a transportation corridor, this is no longer
true.

>MIMO is the basis for all 4G plans- widespread investment in
>developing
>MIMO technologies will ensure advantages are maintained.

It's only advantage in this list you've constructed.

>So, it looks like in all aspects, MIMO is equal to or superior to AAS

Look again - your PRO MIMO statements are far too under qualified.

Somewhere on the internet was a very detailed computer simulation of this. The base is just made so it can not kick out. You have a bending force and a shearing force on the base of a tower. If the base can wiggle some, it will take more stress than if the base is bolted down or placed in cement. It also gets on the climbers nerves when the tower does its shifting.

You can think of this as placing something in the sand or dirt like a yard stick. Place it a couple inches in sand and it will bend way over , place a couple of inches in a crack between some bricks that can not move and start bending it at the top, It will soon snap .

Actually, you'd look at the diagonal braces, too. On several theatrical truss designs, the bending load limit is set by the compression buckling of the diagonal braces, not the tension or compression of the main tubes. A torsional load will put a bending load on the vertical main tubes, but a longitudinal load on the diagonal braces (compression or tension depending on which direction they go). probably also a bending moment on the diagonal struts because they're welded joints.

I don't know what construction technique you have in mind, but I
prefer to build them from 1/2" copper pipe. If that's what you intend
to do, then just cut the vertical radiator 5/8ths instead of 1/2
lambda. Build the rest the same (1/4 wave stub). Attach your coax to
the stub section using hose clamps, and tune by sliding the clamps up
or down until you achieve best SWR. Works great.

Thanks for your replies. I should have made clear that I only left the stake in the ground. There was no radial, nothing else connected to it for those two weeks.

My soil is pretty good (fertile) soil. It's loamy, dry, and dark. I've never measured the conductivity of it. It didn't take too much to drive it into the ground, just a few whacks of my hammer.

Weird!

Jim, thinking about this a bit more...

There are two broad ways to fix the bottom of the tower (if it fixed).

One is to embed the bottom section in concrete, the other is to have a plate on the bottom tower section and fix it to threaded studs / framework drilled or embedded in the concrete base.

The second allows for find adjustment of the plumb of the first section (eg using nuts above and below the plate) wheras the first method does not.

I wonder what the preload on the lower tower sections is if the first section is fixed and not plumb (for whatever reason). Perhaps that is an aspect that the design engineer cannot quantify, so the easy way out is to specifiy pier pin mounting as (properly done) it should eliminate bending moments caused by lack of plumb of a fixed base section.

Source record: 35861

I'm installing a new tower and bought, as part of the package, the grounding kit. This consists of four 10 ft copper clad ground rods, plus all the accessories needed to connect them to the tower.

My problem is that after about 5 feet of good old red clay I hit solid rock. I'm tempted to cut the 10 ft rods in half and simply have eight 5 ft rods. Since this is the only practical alternative that I can see.

Will the eight 5 ft rods give me the same "ground" as the four 10 ft rods? Or, do I need to add even more 5 ft rods to achieve the same ground? (I knew I should have bought that Megger at the hamfest.)

Opinions welcomed. Empirically derived evidence treasured! 8*)

An *ordinary prudent man* would think that one foot
of wire is a "simple series circuit" and it is in a
DC circuit. If as you say, the current in an RF circuit
is the same throughout, why does the current vary
every inch in a circuit with reflections?

Hi Ken,

Oddly enough, you could as easily lay the rods out in a shallow trench (say, a foot deep) and get the same grounding, if not better. The only rule of thumb that might be observed is to not have them in proximity to one or the other. Proximity would mean about five feet in 10 foot parallel trenches.

However, to satisfy convention: cut them in half (or research the archives here for rotary hammers) and keep them isolated, one from the other, by at least three feet.

Ken

This very subject was covered at some length not so long ago. The consensus was that solid rock does not make a very good earth. Driving the rods in at an angle to get the full 10 feet under the soil is probably going to be adequate. If you are concerned that the earth is not good enough, add some lengths of thick, bare copper wire buried in the soil and conected back to a common earth point. The rods are mainly there to provide a dissipation path for lightning if it should hit the tower.

Should it be that simple? I understood from other posters that it will not work with the 1/4 wave stub..
Maybe I must try it myself?

What I found is 2x5/8 wave with a 1/4 wave stub.. ?

I think the rule of thunb is to separate ground rounds by an amount equal to
their length.

The small theroretical gain advantage that a 5/8wl radiator has over a 1/2wl radiator is dependent on it having a very good counterpoise. However one may be able to fabricate a 5/8wl antenna with a couterpoise matched to the feedline with a stub made of metal tubing.

It can be.

> I understood from other posters that it will not
> work with the 1/4 wave stub..

For some posters, a view of the forest is obscured by trees. A j-pole
is a quarter wave stub with a 1/2 wave (or longer) radiator attached
to one side of the open end. The feed is connected nearer to the
shorted end of the stub. Build it and they (the QSOs) will come. Get
it up as high above the roof as you can.

The fact that it's described as having a physical dimension suggests
that the physical extent matters. I don't know what an "ordinary
prudent man" is, but I suppose most people I stopped on the street
wouldn't have a clue what I was talking about and their eyes would
kind of glaze over with the mention of "wire" and "circuit."

I would never do this intentionally but I know of a tower that had its nuts
removed(vandalism) and it stayed up for years like that unti it was finally
demolished. The first requirment on the demolistion procedure was to replace
the nuts. I wonder why because that used small explosive charges to shear
the guy wires on two sides. I t would have made you cry to see all that
tower warped after it fell.

More silly word games - when it is in a DC circuit
the current is constant. When it exists in a simple
series GHz circuit with reflections, the current
is not constant.

A 1/2WL + (1/4WL series stub) is a resonant Zepp.
When the stub is shorted at the bottom and tapped
for 50 ohms, it becomes a typical J-Pole.

A 5/8WL + (1/5WL series stub) is a resonant Extended
Zepp. There is only one resonant point and it may
not be at 50 ohms but it may be close enough. You
won't know till you try it. The feedpoint impedance
can be varied by varying the spacing between the
stub elements.

A 5/8WL + (1/4WL series stub) is non-resonant.
Anywhere you tap on the stub will result in some
reactance. There's really no reason to build
this inferior design.

you don't even need reflections. a properly terminated piece of wire has a
different current at every point along the wire.

Kenneth Grimm, K4XL wrote:
"Will the eight 5 ft rods give me the same "ground" as the four 10 ft rods?"

Maybe better.

Skin effect depends upon conductivity. On copper it is measured in thousandths of an inch but in the earth`s surface, penetration may be 10 or 20 feet.

Skin thickness is also inversely proportional to the square root of the frequency but does not change much sbove about 6 MHz due to electrical capacitance in the soil which makes it appear more of a lossy capacitance (dielectric) than a poor conductor.

Soil with a conductance of 6 mmho/meter has a dielectric thickness of about 8 feet at 6 MHz. A ground rod which would reach the depth of energy penetration is recommended. E.A. Laport says at the end of page 49 of "Radio Antenna Engineering": "Ideally, the ground rods should reach down to the depth corresponding to the skin thickness for the soil conductivity and the operating frequency."

However, using eight 5 ft rods instead of four 10 ft rods would likely improve a grounding system especially if the rods are placed some distance away from their common connection point, say 10 feet or more. The interconnection wiring acts somewhat as a radial system and will have substantial capacitive coupling to the earth at freuencies where the earth`s dielectric properties prevail.

Best regards, Richard Harrison, KB5WZI

That's true but the attenuation factor in one foot
of wire might be hard to measure. Introduce reflections
and even a lossless wire will vary the current from
max to min every few inches at GHz frequencies.

Ken,

Some thoughts...

The main reason for using driven electrodes at the tower base is for lightning protection. I assume that is your purpose.

To predict the effect of driving a number of electrodes, and the depth of driving, you have to consider the effect of the soil. It has high resistivity, and resistivity often changes with depth. Clay soils are likely to be drier at the surface, and higher in resistivity.

So, longer electrodes are often more effective because they reach down to wetter layers, and it is not unusual that an 8' electrode has a quarter the resistance of a 4' electrode for that reason.

Hitting rock isn't necessarily all bad, it sometimes happens that the rock causes wetter clay above it, and shorter electrodes may be quite effective.

You can assess the likely outcome by driving two separated electrodes and measuring the resistance. You can estimate the benefit of driving further adequately spaced electrodes (assuming uniform soil).

Dont overlook using the reinforced concrete base of the antenna as part of your ground system.

A megger! No, if your earth system is any good, a megger isn't going to be useful. There are a number of techniques for measuring the effective low frequency resistance of an earth electrode or earth system. Google for things like the "three wire fall of potential method".

If you can't get sufficiently good earth from driving the electrodes as is, choices include drilling (more effective in soft porous wet rock) or strip electrodes laid in trenches.

As for the 30deg sledge hammer, I put some notes and a pic together on tools for driving earth electrodes, see http://www.vk1od.net/post/driver.htm . The smallest tool was fabricated after recent discussion on using an SDS Rotary Hammer to drive earth electrodes.

All too true. In AM broadcasting, at night the sky wave may interfere with the ground wave beyond the skip zone.

In HF transmissions, the ground wave is likely exhausted in short order so that the sky wave is the only signal available at considerable distances. There will be no ground wave to beat with the sky wave to cause fading but there are numerous paths for the sky wave which produce plenty of fading without adding any ground wave to the mix.

Best regards, Richard Harrison, KB5WZI

TADA! And Jim gets the cigar!

Cecil, you take too narrow a view. at any given instant in time if you measure the current along a properly matched wire you will measure a different current and voltage all along the wire (repeating every wavelength minus losses of course). nothing was stated that required rms, other average, peak, or phasor representation.

If a tower that has a fixed base falls, most of it will be near the base of the tower. If the base is loose and can move, the tower may stay mostly intact and fall and cover a greater distance.

Going by what I read on the Polyphaser site some time back and what BICSI recommends for telecom grounding, a minimum distance is eight feet between ground rods. Closer than that and the rods won't be able to dissipate the energy effectively.

Also, more shorter rods covering a larger surface area of earth is preferable to fewer deeper rods. Minimum length is considered to be 5 feet.

Finally, be sure to tie the tower, shack, and AC entrance grounds together for a "single point" ground to avoid ground potential differences between interconnected equipment.

Hi All,

I ran ClamWin against it, says its fine when compared with 157642
known virii. Anyone with a report to the contrary, and a name to go
with the infection can chime in anytime (who knows when the next Ebola
will arrive, Norton will certainly be able to perform an autopsy after
the fact).

>Norton slowed my computer to a crawl and gave goofy messages like yours, so
>I quit Norton several years ago.

Amen. ClamWin can be configured to check incoming email, but
otherwise is passive until you tell it what to check - a file, a
folder, a disk - for free. It even updates itself - quickly.

Instantaneous values, of course. But, proper termination means no
reflection. The only source of variation along a line other than
attenuation is reflection. In a uniform line, attenuation causes a
steady decline of energy as energy travels. With a lossless line,
properly terminated, variation of rnergy along a line is only the phase
produced instantaneois values along the line. These are resolved during
the period of a cycle by the root mean square calculation.

Not so sure about the tower, I woud bow to Polyphaser's advice but I think
that is suppose to be treated as a lightning ground and have it own ground.
Local codes would also prevail.

IT IS INCREDIBLE!
My beta NEC-Booster is WORKING now!

I implemented the Frequency Sweep (FR-Cards > 1) optimization. For more then one Frequency, the multi-processor / multi-core enhancement of my PC is fully occupied. On my dual-core Pentium, the calculation time decreases almost to half of normal NEC2 calculation time.

I will do now the Radiation Pattern optimization. Especially, if somebody only have one Frequency defined. This part is a non-trivial part and takes some more implementation time.

I need some people as a beta-tester. So I can fix all bugs and special cases.
I will let you know, when I am finished.

michel wrote:
> That is some clear information!! The 5/8 wave version needs a shorted stub
> as well?

What we are looking for is the length of a series
matching stub section that will bring the system
to resonance, i.e. we are looking for the current
maximum point.

The graph at http://www.w5dxp.com/majic.gif
gives the length of the series matching stub
section for dipoles of various lengths from
1/2WL to 1.5WL. The graph can be used for
monopoles by doubling the monopole length.

For instance, doubling the 5/8WL monopole length
gives a 10/8WL dipole length which is 1.25WL.
A 1.25WL dipole needs a series matching stub section
of 0.19WL, i.e. the bottom stub on a 5/8WL J-Pole
needs to be 0.19WL. Make it a little too long and
trim for resonance.

If you double the 1/2WL monopole length of the
J-Pole you get a 1.0WL dipole. From the graph,
a 1.0WL dipole needs a 0.25WL series matching
stub section, i.e. the bottom stub on a 1/2WL
J-Pole needs to be 0.25WL. Of course, that is
the standard J-Pole design.

If you happened to want to design a 0.35WL J-Pole,
the series matching stub would need to be 0.33WL
long. 2(0.35WL) = 0.7WL

Let me know if you understand the graph.

michel wrote:
> That is some clear information!! The 5/8 wave version needs a shorted stub
> as well?

After my first cup of coffee, I canceled my previous
posting. The matching method I described works well
for balanced dipoles but is probably not applicable
to monopoles with no ground plane because the current
in the other leg of the series matching section has
no place to flow in a J-Pole configuration. So a 0.2WL
matching stub is not a good feed design for a 5/8WL
monopole and will generate common-mode problems unless
there is a ground plane into which the current can flow.
Best to stick with the standard 1/2WL J-Pole design. I
apologize for my fuzzy thinking - it made sense until
I woke up. And it would work for a 5/8WL monopole if
it already had ground plane radials.

I suppose that since there will be an antenna current on the stub, and the 5/8 section would show a reactive feedpoint if fed against a ground plane, things are a bit more complicated than just a resistive matching section (the 1/4 wave stub). I would expect that (1) the antenna won't behave quite like a 5/8 wave fed against ground, nor like a 5/4 wave center fed doublet, and (2) the stub will have to be adjusted in length as well as in transformation ratio to get a "perfect" match. In addition, if the feedline is not decoupled from the antenna, the antenna current on the feedline will change both the pattern and the feedpoint impedance (match) from what it would be if the stub+radiator were in freespace.

I'd do some NEC simulating to get an idea of a starting point AND an idea if the pattern was really an improvement over the normal half-wave over a quarter-wave stub, before trying to build one; and I'd put some effort into decoupling the antenna from other nearby metal (including the feedline)--or at least include other elements in the simulation. Even with simulating, I'd expect to have to do some fine tuning (of stub spacing or stub tap point, and possibly of stub

length) _if_ I really cared about a good match.

(Even a half-wave over a nominally quarter-wave stub can benefit from tuning the stub length to get rid of reactance, if you really care about a good match [though that in itself is somewhat over-rated]. With the stub attached, it's not a simple half-wave radiator. There will be antenna current on the stub.)

Cheers,
Tom

> WA4SCA

I bet that code saying you need a 8 foot ground rod for AC, has little to do with its ability to ground an AC current and more to do with it being a common length.
Most every building material is 8 foot long...

and what is wrong with instantaneous values? lacking a requirement to talk
in peak, phasor, rms, or some other averaging method it is perfectly valid
to assume instantaneous measurements. and if I remember right we were
talking of measuring current, not energy. and time is a valid parameter
when measuring current, just hook up your o-scope and measure away...
measure that current on each end of a wire, or coil, or coax, with a dual
trace scope and see the difference! throw away that silly-wire-reader thing
and get back to the basics. get a pulse generator and build yourself a
reflectometer and make use of those reflections!

One way to determine the low frequency effectiveness of a ground is to connect the hot side of the power mains to the ground through a fuse and see how big of a fuse you can blow. There are special devices built for doing this but it can easily and safely be done with less than professional equipment. Just get all the pets and kids out of the way first.

Nothing if presented as part of the context,
confusing if not since most people would
assume the context is RMS. Do I have 110v
AC in my house? You can argue that the answer
is "no" but you would need to state the context.

Well, yeah! :-)

But there is a standard test for ground conductivity. Some pros told me how
they do it.

Drive three ground rods, A, B and C along a line. Pass a known current
between A and C. Measure the voltage drop between A and B. Ohm's Law will
give you the resistance at that place. I don't personally know what a
"good" number is for that test -- however,
http://mrtmag.com/techspeak/radio_wellgrounded_principles/ suggests 10 ohms.
These guys http://www.rainmaster.com/pdf/TB025C.pdf say the NEC wants no
more than 25 ohms.

I suppose if the soil conductivity is poor, multiple interconnected rods are
advisable/required.

You are measuring the resistance of the A electrode in this case. A could be a ground system (ie more than one electrode).

There are some rules to follow wrt spacing of B and C from A. Worth a read of how it is done before making dodgy measurements.

Commercial instruments using this principle may use an internal AC generator somewhere around 1kHz with a synchronous detector, and chosen to be in between the harmonics of 50Hz and 60Hz, so they can make measurements that are less disturbed than measurements that are susceptible to 50Hz or 60Hz ground currents from other things. Yes, you can make measurements of a ground electrode connected to an working AC installation... so long as the electrode voltage due to the 50Hz or 60Hz current is too great.

In this part of the world, the relevant standard requires that the entire lightning protection earth system has a resistance of less than 10 ohms before equipotential bonding to other services.

Not really that dangerous if you know what you are doing and as far as precesion goes all you really want is a less than some number value. In the case of the power company everything is good if you can pop a 4 amp fuse. The PoCO has a special device for doing this. It looks like a breach loading shotgun with a pistol grip. Just plug it in to an outlet, put in the fuse and touch the barrel to ground. Working on a hot chassis is probably more dangerous than this even if you had to cobble up some way of doing it .

> 73, Cecil http://www.w5dxp.com

It's not the matching scheme that is the real problem..
A single 5/8 radiator over no radials is going to be a real
dog no matter how you match it.
And if you do use radials and a 5/8 radiator, you might
as well feed it with a simple series loading coil.
I've never been a great fan of J-poles, but if I were to
build one, it would be the standard 1/2 wave version.
If one is going to build a copper J pole using 5/8
elements, they should use two and build it as a
collinear. And even in that case, there should be a
decoupling section added for the best performance.
My favorite "cheap and easy" antenna for VHF is
not the j pole.. It's the 1/4 wave ground plane with
sloping radials. It's easier to build, needs no matching,
and the gain should be very close to most 1/2 wave
j poles.

The best "counterpoise" for a 5/8 radiator is a set of 5/8 radials...
But in that case, it's more of a collinear.
Myself, I think a 5/8 radiator should always be used with a 5/8
lower section of you want the full performance. IE: dual 5/8
collinear.
Anything else is a perversion... :/
My 2nd choice would be to use 3/4 wave radials.
1/2 wave radials would be useless.
1/4 wave radials are semi useless, and give a lousy pattern..

In my search on vertical antennas I also found a option to add on a 1/4 wave
element a 5/8 element. This needs a phasing coil?
I also found a 5/8 element mounted over a 1/4 innerelement.. ?

But wat is the best for homebrew, and a few dB gain?

I found them to work quite well, though I fine tuned them on the mast
- not in the garage next to the transmitter.

Amen, bro. Another advantage of the ground plane: the radials decouple the feedline from the antenna. In a J-pole installation, either you put some effort into decoupling the feedline, or you accept that the feedline is going to radiate (and change the pattern). (I suppose yet another option is to deny the fact that feedlines can radiate...)

It's easy to build a "quick-and-dirty" 146MHz ground plane with an SO-239, some 4-40 screws, washers and nuts, and three lengths of 12 or 14 AWG copper wire. A couple half-wave lengths attach to the flange of the SO-239 with the 4-40 hardware (or just solder them) so there are 4 1/4 wave wires sticking out from the flange; a 1/4 wave piece solders into the center pin. The radials can be bent down a bit to

get a match to 50 ohms. You can put a little loop in the top of the radiator and hoist it into a tree with fishing line or the like. There are several ways you can attach it to the top of a mast; it doesn't care a lot about what you do below it.

Cheers,
Tom

The only electromagnetic currents 'flowing' on a transmission line are the currents which result from the reflected and/or the forward electromagnetic waves. Neither of these currents varies periodically along the line (except as noted, instantaneously).

With VHF verticals, half the battle is decoupling the feedline.
It's no use worrying about extended verticals, unless you also
consider decoupling the line. Radiation from the line will skew
the pattern upwards off the horizon, and any gain from extended
radiators will be useless.
If you are going to use a 5/8 radiator, I would go whole hog and
build a copper collinear with dual 5/8 elements. I wouldn't waste time
with other versions. And even the dual 5/8 collinear needs a
decoupling section of some type.
One reason I like the 1/4 wave ground planes is that they naturally
decouple from the feedline fairly well. The more radials you use,
the better the decoupling, and if you add a 2nd set that is 1/4
below, you will have very good decoupling.
That method can be used to decouple a dual 5/8 vertical.
I would worry more about how the line will be decoupled, than
I would element length. It's more important.

A 3/4WL vertical monopole has a take-off-angle of 47 degrees.
5/8WL is the length limit for good monopole DX performance.

Having made a couple of whip+radials antennas out of old coathangers, I
am not at all hostile to your views.

However, as a fan of the j-pole, myself, I offer their ruggedness as a
distinct advantage. My first copper pipe j-pole (from the early 1990's) is
still on my roof. It has turned a slightly darker color but is otherwise as
good as new. I made three for our Fire House RACES station (two 2m & a 6m)
and they will outlive me.

Just my $0.02.

Hello,

my NEC2 Booster with multi-core / multi-processor support stucks at the moment. On Radiation-Pattern-Division (each core computes an interleaved part of the global RP-command), with different input file calculations, I got different Average Power Gain values for each calculation. The calculated results of each core have to be merged together.
How can I compute the exact Average Power Gain (APG), using the Radiation Pattern values listed below? Is it at all possible to compute the APG, using the Radiation Pattern data?

Or should I take the stupid average of the APGs of each core?
This question concern also to SOLID ANGLE USED IN AVERAGING(xxx) handling.

Please help me. The more you wait, the more you will wait, till I am finished!
I intend to give the NEC2 Booster for free as soon as possible.

Regard,
Aziz

Here's a fun experiment with EZNEC.

1. Open the VHFGP.EZ example file. Click View Ant to open the View Antenna display. In the View Antenna display control section, click Center Ant Image so you can see the antenna better.
2. Add the following wire:

End 1: 0, 0, 5 (wavelengths)
End 2: 0, 0, 4.727 (wavelengths)
Diameter: 0.25 (inches)
Segments: 6

This represents the outside of a feedline connected to the feedpoint.
3. Click the Currents button. Look at the display and, in the Currents box, compare the current on the outside of the "feedline" (Wire 6, Segment 1) to the main radiator current (Wire 5, Segment 1).
4. Change Plot Type to Elevation. Click FF Plot to see the 2D elevation pattern.
5. Reconsider the statement about decoupling. . .

This is admittedly contrived to show a particularly extreme case. But try different lengths of "feedline" either open or connected to ground and you'll find other cases where the feedline current is high and the pattern distorted. You'll also find cases where inserting a "balun" (high impedance load) in the "feedline" will actually increase the feedline current due to changing the current distribution to a value more favorable for the particular feedline length.

Hello,

Will be buying one of the new GRE hand held scanners soon.
Like all handhelds, it comes with the relatively short vertical whip antenna coming out of the top; I guess they are also termed rubber-duckies.

Not all that sharp with antenna theory:

My guess is that when held vertically, it is optimum for receiving verticall Polarized signals, and my guess is, also, that all P.D.'s and Fire Dept transmitters use vertically polarized signals.
Is all this correct so far ?

a. What happens if I lay the radio, with the antenna too of course, hotizontally on its side ?
Will it still pick up "anything" ?

b. Transmissions from airplanes: is there any meaningful polarization from their antennas, or is it pretty random by the time it reaches the ground, such that any any antenna orientation would be pretty much the same ?

Thanks,
Bob

yes, 'rubber ducks' are not all that directive, though they will have a null
off the top and bottom that may be pretty good.. you would likely want to
avoid laying it on its side on a conductive surface as that may affect it
more than the polarization change.

>
> b. Transmissions from airplanes: is there any meaningful polarization

yeah, pretty much. though for high angle paths a vertical antenna may
produce a null that reduces the signal. but on the bright side they can't
be all that far away if they are almost overhead so the signals are stronger
to start with.

I'd be curious to see what you get doing the same with a 1/2 wave
whip.
IE: usual j-pole, 1/2 wave whip...
I tried doing a test using the demo version. Being it was limited
segments,
I tried to keep it even, and used twice the segments for the 1/2 wave
radiator vs the 1/4 wave, but used the same amount of segments for
the "feedline" .
I also used "real ground", and the elevation plot so I could more
easily see the appx real world plots.
With the GP, I notice heavy current when the feedline is appx 1/4
wave, but not so bad when it's longer. In some cases I saw a gain

where the feed currents seem to be in phase with the antenna
currents.
When trying the 1/2 wave, I didn't see the problem too much using a
short 1/4 wave feed, but the longer lengths were much worse than
the plots for the GP.

1/4 WL GP

6.58 dbi at 3 degrees -no feedline
5.26 dbi at 42 degrees -feedline .28 wl
7.39 dbi at 3 degrees -feedline 1 wl
6.09 dbi at 3 degrees - feedline 2 wl
6.77 dbi at 3 degrees - feedline 3 wl
7.05 dbi at 3 degrees - feedline 4 wl
7.87 dbi at 3 degrees- feedline 5 wl and grounded at "0"

1/2 WL whip

6.43 dbi at 3 degrees -no feedline
6.84 dbi at 3 degrees -feedline .28 wl
6.23 dbi at 3 degrees -feedline 1 wl
6.67 dbi at 55 degrees - feedline 2 wl
14.82 dbi at 68 degrees - feedline 3 wl
21.42 dbi at 67 degrees - feedline 4 wl
6.68 dbi at 3 degrees- feedline 5 wl and grounded at "0"

Anyway, I may have had problems running this
test with the limited segments, but it seems to
show the 1/2 wave as having the worse problems
of the two overall. Really bad at 3-4 waves length
of line.
So while the decoupling for the GP is not always the
greatest, I think it's still probably less a problem
than the usual 1/2 wave whip with no decoupling.
I've never used chokes or baluns per say to decouple
a VHF vertical. I always use radial sets, cones, sleeves,
etc..
The usual ground plane really needs two radial sets to
decouple the line well. Most good sleeve dipoles will
use an extra sleeve for decoupling the line.
You might get a bit different results using unlimited segments.
But I betting the trend will still be fairly close, with the
non-decoupled 1/2 wave being the worst overall at the longer
line lengths.

Jimmie D. wrote"
"One way to determine the low frequency effectiveness of a ground is to connect the hot side of the power mains to the ground through a fuse and see how big of a fuse you can blow."

Replace the fuse with a light bulb. If a high-wattage light bulb burns brightly, the earth connection is good at the power frequency.

Higher?? You posted 6.34dBi for the half wave, and 6.58dBi for the quarter wave GP ... Am I misreading something, or was that a typo about which has higher gain, or what?

Thanks for taking the time to make the simulations and posting the results, Mark. And thanks to Roy for pointing out that the GP doesn't fully isolate the feedline from antenna currents. I should say "pointing out once again" as I know he's posted it before, now that I'm reminded about it. I don't have time at the moment, but put it on the list to play with in simulations when I have some time.

Still, the 1/4 wave GP is extremely easy to hack together in an emergency -- you can even strip a quarter wave of braid off coax and twist copper wire or coat hangers around the top of the braid for the GP -- and should perform comparably with other more complicated antennas. A plus is that you only need to remember (or figure out) how long 1/4 wave is to know how to cut it to get a decent, if not perfect, match.

Cheers,
Tom

Dang.. I guess I had it backwards in the 2nd post...
Normally, I would think the 1/2 whip would show slightly higher,
but dunno.. Quiver in the force I guess.
I have no real problems with either type. A 1/2 wave whip is fine
if it's decoupled.
But few J pole users seem to add decoupling sections.
Most of the ringos sold for VHF lack decoupling also..
One note.. If I build a 1/2 wave, I usually prefer to feed as a ringo,
vs as a J pole..
But I still mostly use the GP's as they are simple. I've got one up
in the attic hanging from the rafters as an emergency antenna
when T-storms are in the area and I'm chicken to use my outside
antennas.

Yes, BUT, the 5/8th wave radiator will put more of the signal toward the horizon, instead of launching it at a 40 degree plus angle away from the horizon. So while one configuration can have higher dbi ratings, it doesn't count unless the signal goes where it will be most effective.

I have a friend (engineer) that designs and builds his boats (some rather large sailboats) with everything quantized mathematically. I showed up one day with a model sailboat sitting on a carry stand that I had made. He asked me how I calculated the angles needed to accommodate the hull accurately. He said that this problem had been bugging him for a while. I was surprised because this guy is really smart.

I grabbed two rulers and put each one along the side of the boat and then clamped them at that angle. I then transferred the angle of the two rulers to a sheet of paper by simply drawing lines along the inside of the v that was created. His jaw dropped in surprise. He was amazed at how easy the process was and he realized that the same process would work with his full size boats. No math required.

While EZNEC is a fantastic program, it is no better than the programmer that wrote it. No one person can take absolutely every variable into consideration because many of them are very, very complex and nearly impossible to quantize.

I suggested a simple 1/2 wave J-pole antenna earlier that was easy to make, super easy to tune and one that worked very effectively. Yet everyone is beating their brains out trying to come up with the best 5/8th wave J-pole, even though this design will require lossy matching devices to get the impedance down to a manageable/acceptable level. What's up wid dat?

I do realize that figuring out such a design is fun in and of itself and may be the real purpose of the exercise. Still, I'll betcha no one on the receiving end of the OP's signal could tell if he was using the 5/8th wavelength J-pole or the 1/2 wavelength J-pole.

It is an interesting topic for modelling.

I wrote some notes up after modelling an unloaded elevated vertical as a multi-band HF antenna. I was particularly interested in the effectiveness of decoupling of the mast / feedline and the loss implications of mast current flowing to ground. The article is at http://www.vk1od.net/multibandunloadedvertical/13mEV.htm . The spikes in loss in Fig 3 and 4 are mainly due to loss in the simulated resistance of the earth connection at the lower end of the mast.

So, the issue is not just about pattern distortion, efficiency may be impacted significantly.

One of the popular antennas amongst our new six hour hams is to use their StationMaster on 40m and 80m The StationMaster is a half wave vertical for 27MHz base fed with a parallel tuned circuit and the 50 ohm coax is tapped onto the coil of the tuned circuit. (A 27MHz version of the once popular ham ringo... but the coil is multi turn.)

When modelled on a 10m high mast on 40m and 80m, most of the current moment contribution is from the support mast and the efficiency is low due to losses in mast current flowing to lossy ground. Additionally, there a huge transmission line losses. It is a top fed dummy load... but with the magic of an ATU, it has a VSWR of 1:1!

But, when their investment in ham radio is 6 hours of learning, they aren't well equipped to appreciate that the StationMaster isn't an efficient antenna on 40m and 80m.

Dunno.. You sure you ain't got it backwards? Unless the 5/8 is on a
large
ground plane, etc, it's usually the one with the higher avg launch
angles
vs the 1/2 wave.
The 5/8 with no radials should be pretty bad at that.. Even a set of
1/4 wave radials under a 5/8 will give a fairly poor pattern.
If I were to build a j pole, it would be a 1/2 wave.
If I run a 5/8, I'd have two elements as a collinear, or at least
have 5/8 or 3/4 wave radials. I'd never run just a single 5/8 wave
radiator
on it's own. It's not a "complete" antenna like a 1/2 wave j pole is.
Or to my way of qualifying anyway...

Yet another calibrated screw driver approach. The undefined quantities "high-wattage" and "burns brightly" characterise the accuracy of the method.

There are simple and safe methods for passing a known or measurable current through a ground system and measuring the ground system potential rise above the general mass of earth... a bit of Googling will turn up far better methods that some of those described in this thread.

Dave,

"should" being the operative word.

It isn't always the case that feedline radiation is insignificant. Keep in mind that the transmitter feedline might also be much closer to the affected device, its power line and its feedline.

It is also fair to say that there is a whole family of ham myths that revolve around feedlines being the cause of RFI, TVI, generation of harmonics, causual links between open wire feedline and interference, etc.

Surfin': Linuxating VOACAP

By Stan Horzepa, WA1LOU
Contributing Editor
October 05, 2007

Jari Perkiömäki, OH6BG, wrote recently to inform me that VOACAP, the free professional HF propagation prediction program from National Telecommunications and Information Administration's Institute for Telecommunication Sciences (NTIA/ITS), is now available as a Linux application. In addition, VOACAP now has a graphical user interface (GUI) to make inputting and outputting data easier.

VOACAP is the initialism for Voice of America Coverage Analysis Program (for HF Propagation Prediction and Ionospheric Communications Analysis). It may be an acronym, too (vo-ah-cap), but I cannot attest to ever hearing anyone using it that way.

VOACAP is the result of more than 50 years of US HF research and development and many consider it to be "the most professional HF system performance prediction tool available on the market." VOA and other international HF broadcasters currently use the program for HF frequency planning.

Originally a UNIX program, the official release of VOACAP is a Windows program. This project represents an effort to compile the program's source code on Linux/Mac OS X. Take a look at Jim Watson's, M0DNS, VOACAP on Linux Web page for source code, output scripts, installation information and such. Also, check out Jari's VOACAP Quick Guide for general information about VOACAP and the new GUI.

2015. The varmints [not the dog] chewed my ladderline!

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-06 02:47:24 UTC
From: Joaquin Tall <opalockamishabob@netscape.net>
Message-ID: <FYednUsI6_ONa5vanZ2dnUVZ_vOlnZ2d@nethere.com>
Source record: 35697

Hello All,

Brisk winds blew through our area yesterday and, unfortunately, my 200' G5RV's feedline touched ground overnight.

This morning I noticed that there were chew marks over 40' of the ladderline; most went deep enough to expose the copper wire underneath. We live in the country...

I called the manufacturer; they told me that "splicing/soldering" in a 40' length of 300 ohm line to replace the chewed up line would upset the SWR and almost make the antenna useless. It's the solder joints [no matter how small] that would mess things up.

I used some silicone calk to cover the bite marks; ever try to smooth out calk on twinlead!?

Do I need to remove/replace the feedpoint and the 40' of the twinlead, in other words make most of the antenna over again?

Any options to make the antenna whole again, the above draconian measure notwithstanding?

Many thanks for taking the time to repond!

Alain

It's remarkable how there's a new flavor of baloney posted here at
least once a week.

>It's the solder joints [no matter how
>small] that would mess things up.

Sounds like a McHales Navy re-run from that crew you called.

>I used some silicone calk to cover the bite marks; ever try to smooth out
>calk on twinlead!?

Real easy if you use a wet rag or just wet hands. Wet is the keyword
and it is water cured.

>Do I need to remove/replace the feedpoint and the 40' of the twinlead, in
>other words make most of the antenna over again?

You don't even need to silicone calk it. Insulation is not all its
cracked up to be either (the copper is already insulating itself as we
pass these messages back and forth).

>Any options to make the antenna whole again, the above draconian measure
>notwithstanding?

Lift it back up in the air and fire up the rig. After all, you didn't
notice you had a "problem" until you LOOKED at it, did you?

Now, the chances are you are going to be hypersensitive about any
changes you make, or you don't make. It will SEEM that the antenna is

not operating as it had before. Blame it on the weather, it wasn't going operate the same as it had before anyway - even if it never fell - even if the bugs hadn't chewed it.

Because feeders often pass near consumer electronics.

If the feeder has no antenna currents on it (like my feeder years ago when I had a vertical 250 feet out from the house), then the antenna, while radiating much more than the feedline is far enough away that the inverse square law protects the consumer electronics.

Of course this depends on antenna placement.

Content-Type: text/plain; charset=ISO-8859-1; format=flowed
Content-Transfer-Encoding: 7bit

Hi:

Let's say I am in a space station which has a 2 GHz DX AM analog receiver that receives the magnetic fields [while ignoring the electric fields] of extremely weak 2 GHz AM analog carrier signals. In addition, this receiver is so sensitive and powerful that it can clearly pick up AM carrier waves as weak as 10-to-the-power-NEGATIVE-10,000 watt-per-meter-squared. This receiver also has a robust signal processor that can eliminate clipped-waveforms [such as square waves], spikes, clicks, pops, hiss, and random noise even at those trivial wattage levels. After eliminating those unwanted signals, the carrier wave is amplified. This receiver has an astronomically-powerful amplifier which amplifies those extremely-soft carrier waves until the resulting modulation signals will be just loud enough for the human ear to coherently detect. Following this amplification, the carrier waves are demodulated to modulation waves -- the stuff we "hear" -- and then sent to loudspeaker so those onboard can hear those sounds.

Equally important, the 2-GHz receiver is pointed away from the earth to assist in preventing the pickup of signals generated from Earth.

If I am on this spaceship, what will I most likely hear on the radio?

Thanks,

Radium

I like the 5/8th on VHF because it has noticably more gain than a
1/4wl groundplane and in my opinon is easier to build and match than
an end-fed 1/2wl antenna.

> Of course this depends on antenna placement.

The improvement noted by increasing the distance between the radiating conductor and the consumer electronics (or power or other wiring they're connected to) can be much greater than an "inverse square law" would imply.

That's because a lot of the problems with interference occur in the near field of the radiating conductor. In the far field, the field strength is inversely proportional to the distance (the power density follows the "inverse square law"). But in some parts of the near field, the field strength varies as the inverse *cube* of the distance. So even a small increase in distance can often have quite a dramatic effect on interference level.

Depends on where you are. Electromagnetic emissions from the Earth greatly increased after WW II with the advent of widespread television broadcasting. This resulted in a veritable step function in the sphere of energy expanding as it races away from the Earth at the speed of light. On the very leading edge of that sphere of energy are the Howdy Doody Show and the McCarthy hearings. This explains why no aliens have ever visited the Earth. But it sounds like programming that's right up your alley. If you can find that sweet spot in space, sit back and enjoy.

Tried that, I couldnt discern the difference between a 10 ohm ground
and a 25 ohm ground. The "blown fuse method" really works well and is
no where as dangerous as people make it to be. I Have a little deal
made up out of PVC pipe with a fuse holder and neon indicator to let
me know whether the fuse blew or not.

Please tell me, how is this any more dangerous that troubleshooting
under the chassis of a tube receiver.

There is no carrier, it was one of those signals you just
eliminated.

The manufacturer is really blowing smoke, You could replace the
feedline, insulate with silicone, or just dont do anything as long as
the wire isnt damage. twinlead works just fine with bare wire.

its the impedance, not the solder joints, that would mess things up. if you
got a piece of the same impedance ladder line you could spice it just fine.
but as long as the bite marks don't break the wire then adding a bit of
caulk is as good as anything else to fix it for now.

That mfgr is not just blowing smoke, he's making an erroneous statement , hoping you'll bite and buy some more
of his product, and at the same time starting another myth that we don't need.

If you're using 300-ohm line I assume you're also using an antenna tuner to match the line to the transmitter.
If this is the case then the line impedance is immaterial, because you could remove the chewed-up portion and
replace it with 450-ohm or 600-ohm line, or whatever impedance line, and adjusting the tuner for an input of
50 ohms will have compensated for the different line impedances along the way. The only result from using
different line impedances is that the SWR will be different on the line sections having the different
characteristic impedances.

The length of 450-ohm line I had available wouldn't reach from the tuner to the terminals of my 80-meter
dipole, but I had a lot of 300-ohm line. So I just used the 300-ohm line to make up the shortfall in the
450-ohm line. Works just fine. Yours will too.

Hash: SHA1

Hi, I'm a new ham, and I'm looking for my first HF transceiver. I am
considering the Yaesu FT-817ND. I did some google searches and could not
find any information about using an antenna tuner with this rig. How can
it work on all bands without a tuner? Would I need a tuner or does the
supplied antenna work on all bands without a tuner? I browsed the
owner's manual on Yaesu's web site as well and didn't see any mention
about using a tuner. The link to yaesu's page is
http://www.yaesu.com/indexVS.cfm?cmd=DisplayProducts&ProdCatID=102&encProdID=06014CD0AFA07
02B25B12AB4DC9C0D27&DivisionID=65&isArchived=0
I read some reviews on eHam too, and it almost sounds like the FT-817ND
doesn't need a tuner.. I'm confused.
Any opinions would be helpful.

Thanks!
Jim

You dont have to do it that way, You are assuming the worst possible
condition. It can be done safely.

Depends on what you call "better". Blowing a fuse is cheap, accurate enough
for most practical purposes and people with reasonable common sense and
experience with electricity can do it safely. If more accurate results are
required, If your experience level will not allow you do do it safely then
by all means find some other way.

I'm not sure what you are referring to regarding the "supplied antenna". The FT-817 does come with a small VHF antenna for 2 meter operation, but like all other HF transceivers, it does not come with any HF antenna. You can build yourself some dipole antennas for the bands you want to operate on.... they would be resonant and have a 50 ohm feedpoint so you would not need any tuner.... (the output connection to almost all radios has a 50 ohm impedance). If you want to use a non-resonant antenna, then an outboard Tuner should work fine.... as long as it is capable of operating at low power levels of 5Watts or less. LDG Electronics makes some fine QRP type tuners. My old LDG Z-11 tuner works great with my FT-817.

If I remember correctly the oft quoted theorotical gain of a 5/8ths is with
a groundplane that extents to infinity.
5/8ths with sloping 5/8th radials are begining to perform more like a
ceterfed collinear.

Until recently, I owned an all fiberglass houseboat--beautiful rig.
However, on fresh water it offered no counterpoise properties whatsoever.

A continuously loaded 1/2 wave end fed vertical utilizing a modified
gamma match feed ended up the solution, and one which required a minimal
counterpoise.

Hi Jimmie,

Sounds like the passionate "Trust me" every teenage boy assures his
date in the back seat. "We can do this safely if I don't...."

With a nearly infinite amount of current behind the fuse (the part of
the wire you are closest too) and standing on an nearly infinite sink
of current; sure you can do it safely IF... (with a chain of
conditions that must be all met, with any one of which that fails
results in death).

You are not going to buy this device off the shelf, certainly no
vendor could afford the liability. You have to expend some effort
(however slight) to build it yourself. It then argues, with the same
effort, why don't you do it right?

An equally (possibly more) accurate method might be as simple as
digging up a spadeful of earth and counting the worms. If you can't
sink the shovel, you already know you have poor earth and you've saved
the cost of a fuse-blower.

The transceiver's output circuitry makes it work on each of the bands,
1.8 through 440 mhz. An antenna tuner has nothing to do with that.

If you attach a resonant antenna for a particular band, it should work
fine with the transceiver on that band. If the antenna feedline does
present a 50 ohm impedance to the transceiver, you may need an
external antenna tuner.

Roy,

The NTIA's long awaited second report on BPL has some interesting results of NEC simulations to support the Part 15 distance extrapolation factor of 40dB/decade on slant distance below 30MHz. NTIA have models at a range of frequencies that explore the validity of the above factor, part II which contains the graphs of the simulations makes an interesting read.

It seems to me that the issues to do with field strength vs distance are quite applicable to a ham antenna as the radiator.

The report is at
http://www.ntia.doc.gov/osmhome/reports/2007/bpl2007.html .

Yes there is. Why do you say there isn't? Certain waveforms in the
carrier wave that would cause the modulator signal to contain
clipped-waveforms [such as square waves], spikes, clicks, pops, hiss,
and random noise are removed. However, the remainder of the carrier-wave
remains unscathed.

I don't troll or spam. I am asking this question because -- unlikely [if
not impossible] as my 2-GHz-in-outer-space scenario is -- I am still
interested in it.

Now please please please answer my question. What would I hear?

I chose 2 GHz because it is in the UHF band. UHFs tend to be best for
extremely long distance reception. Of the radio waves emitted by objects
trillions of miles -- or more -- away, UHF is usually the most receivable.

Bob,

Before the new ham becomes totally confused, I think your typo above should be corrected.... If the antenna feedline does NOT present a 50 ohm impedance to the xcvr, he may need an external antenna tuner.

I'm a new ham using the FT-817ND. I wish I had gotten a 100-watt rig as
my first transmitter and gotten the low-power 817ND later. I do like
the idea of QRP (low power) operation but it requires patience and some
experience with knowing when the bands are open. Probably not the best
choice for a new ham.

> I did some google searches and could not
> find any information about using an antenna tuner with this rig. How can
> it work on all bands without a tuner?

For the frequencies above 30 MHz you can use the whip antenna that
comes with the 817ND. No tuner will be needed.

For the frequencies below 30 MHz you need some sort of outdoor antenna.
You can find some ready to use antennas at the MFJ Enterprises web site
among many other places. One example of a way to go is this. Get a
simple dipole antenna for the 80 meter band and install it outdoors.
You can use that antenna on the band it's made for without a tuner.

With the help of a tuner (such as the automatic Z-11 Pro by LDG
Electronics) you could also use that antenna on higher frequencies such
as the 40 meter band, the 30 meter band, etc.

sincerely,

anonymous in Florida

> . . .

When mounted on a perfect ground plane of infinite extent, any ground mounted vertical monopole higher than 1/2 wavelength will have one or more high angle lobes. As the height increases above 1/2 wavelength, the gain at the horizon increases even though a high lobe appears at around 60 degrees above the horizon. The gain at the horizon peaks out at about 5/8 wavelength, where the high lobe is about 9 dB weaker than the main lobe. As the antenna gets longer than 5/8 wavelength, the power going into the upper lobe starts reducing the gain at the horizon (and the lobe's elevation angle slowly drops) until at one wavelength, all the power goes to the upper lobe and there's no radiation at the horizon at all.

The gain increase of 1/2 or 5/8 wavelength antennas over shorter monopoles comes about by a narrowing of the lobe pointing toward the horizon. Unfortunately, though, radiation at the low angles is severely attenuated by reflection from real ground. And this is just where most of the power from longer verticals is going. So a 5/8 wave HF vertical usually won't exhibit the gain over a shorter antenna you see with a perfect ground simulation. Likewise, a finite ground plane like a car roof impacts low angle radiation, so it has more of an effect on a 1/2 or 5/8 wave radiator than a shorter one, and once again you often won't see the gain you might expect.

A few minutes with the demo version of EZNEC or a similar program shows the effect of finite ground on various antenna heights very clearly. Use MININEC-type ground to eliminate the separate effect of ground system resistive loss. The full EZNEC program will let you model an antenna on a car top (by using a wire grid to simulate the car top).

Actually you CAN buy it off the shelf. The local power company uses them and they ARE factory made devices.
The biggest difference between theirs and my homebuilt one is theirs is breach loading which gives them the ability to safely change the fuse without unpluging it. I think mine has a better feature, the business end is sheathed and has to be fitted down over the ground connection on theirs where you contact the ground the electrode is EXPOSED. Yeah you might get electrocuted doing something like this, you might get yourself impailed on a groundstake while driving it and you might get in a bad wreck the next time you are out fox hunting. Everything has risk. Knowledge, skill and common sense can mediate a lot of it.

I check the ground on 28 facilities twice a year and the most dangerous part of the job is driving to the facilities.
Now that can be scary.

Not entirely. Goalie equipment is still sold, and people like me can send
a puck at them approaching 100 mph. Liability is a big part of the price.
Similar to climbing harnesses. Or tube equipment for that matter.

I dunno, it doesn't seem like that bad of a solution to me. But then
again, I dig my radial trenches with a chain saw. 8^)

It more that just the car's roof that impacts the antennas' radiation
patterns. The car's whole body has a significant effect and there will
be variations - sometimes large - between different vehicles.

>
> Jimmie

Exactly. That is what you want. A 5/8 element is only half an
antenna,
and the other half wants to be a 5/8 too to work properly. All a 5/8
GP
is , is half of an EDZ. You would never want to run only half of an
EDZ,
or use a 1/4 wave leg on one side, etc.. Like I say, it's a
perversion.
The 1/2 wave is the only single element that can be a proper complete
antenna on it's own. Or according to the laws of NM5K anyway... :/
And of course, even that "complete" antenna needs decoupling from
the feedline to live up to it's full potential.
The success of a 5/8 antenna varies a lot across the spectrum.
On 2m, I hate em... Not a good pattern for VHF, unless you use the
collinears, etc..
But... On 10m, it's my favorite vertical.. I've done careful tests
over
the years, and I've never had any other type single element beat it.
But... I was using 3/4 wave radials the last time I did do testing
on all those.
In one test, I started with a 1/4 wave GP with sloping radials.
Worked ok..
Then I built a 1/2 wave whip, and fed as a ringo.
I saw an improvement over the 1/4 GP, even with no decoupling.
So, I then decided to add a decoupling section, using a 1/4 wave
section of the feedline below the feed, and attached to a set of
1/4 radials.
This improved the antenna a good bit. It was really humming
along at that point. I used mainly stable local signals to test
any improvements. When I added the decoupling to the halfwave,
I noticed a bit less bandwidth as far as the antenna, but the
performance was more stable, and I assume would be about the
same no matter what line length I used, etc..
Anyway, I had the half wave working about as well as possible I
think.

Then I built a 5/8 radiator, and used 4 sloping 3/4 wave radials.
Guess what? It beat the decoupled half wave by an easily noticed
margin on the low angle space/ground wave paths I was using to
test. The other stations were spread across town in various
locations, some 30-40 miles away.
If the low angle performance of the 5/8 was crippled, I sure
didn't see it here on 10m. It still had enough gain at low angles
to beat anything else I could try.
BTW, all those antennas were mounted at the same 36 ft height.
I also ran a 5/8 GP on 17m for a while. That antenna beat every
other antenna I had that could be tuned for 17m. IE: wire
dipoles, etc..
I've seen a load of people use the usual "perverted" 5/8 GP
on the CB band. Even with the short 1/4 radials, I never saw
one of those lose to a 1/4 wave GP. On the average CB meter, '
the change from a 1/4 GP to the 5/8 GP was normally good
for about 2 S units on the average CB , if you were talking
across town a ways. I've seen this too many times for it to
be a fluke of nature. This goes back to the early 70's..
Anyway, I like 5/8 verticals on the HF bands. But myself,
I don't use the short 1/4 wave radials.
As far as 5/8 whips on cars, just depends on the path.
Here in Houston, with the flat terrain, a 5/8 will generally
beat a 1/4 wave by a noticable amount, and will usually
have less picket fencing.
But in those cases, the metal under the antenna is fairly
large vs wavelength. IE: a 5/8 at 146 mhz is about 48 inches.
So it doesn't take a huge vehicle to give a decent ground
plane if the antenna is on the roof or trunk.
Myself, I think most mobile 5/8 whips work better than
elevated 5/8 GP's used on the same band.
In some areas, the terrain will favor using the 1/4 wave
though.
Like I say, the usual 5/8 with 1/4 wave straight radials
is generally the pits on 2m, unless some strange quiver
in the force kicks in, like say in phase feedline currents,
etc. And thats fairly rare in the real world. It can happen
though..
A properly decoupled dual 5/8 collinear on 2m is a stout
antenna and will be hard to beat unless you take drastic
measures. Once I get to that point, I switch to a yagi if
I want to do better. A 3 el yagi will pretty much smoke
any practical vertical.
Anyway, the performance of 5/8 antennas varies quite
a bit depending on where you are using them at.
The 5/8 with 3/4 radials I used on 10m was pretty
stout overall. It was the best out of all the usual
lengths.
The real world and the modeling programs don't always
exactly jive..

IE: On Cevics page, he mentions that in his modeling
tests, he seems to think the 5/8 GP was generally
not worth the trouble on the upper HF bands.. IE: 10m
I know from real world use, it is worth it. No doubt
in my mind. But I also know there are much better
radial lengths than the straight 1/4 wave.
BTW, I agree with one thing he mentioned..
Sloping 1/4 radials with the 5/8 is the pits... You want
1/4 wave radials straight out if they are under a 5/8
whip. Sloping them will really whack out the pattern.
But sloping radials are no problem under a 1/4 wave
whip. Now, on the other hand, sloping 3/4 or 5/8
radials under a 5/8 whip are ok.

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

A few years ago I bought a commercial 5/8ths with sloping 1/4 wl radials, It was worse than the homemade 1/4wl groundplane it replaced.

> choice for a new ham.

As someone who is on the other end of the signal path, I can tell
you that 100 watts is not going to make much of a difference if the
band is not "open".

Your signal would be stronger and the two "S units" or so may bring it
above the noise (or not), but if I can't hear you at all, 5 watts,
100 watts, 1000 watts, or even 100,000 watts is not going to make
your signal show up somewhere there is no propigation to.

It WILL help for crowded bands, where hearing your signal a little louder
than the others, or at least not being lost in a pile-up, but that comes
back to skill and patience.

Timing is also critical, when I can hear U.S. stations it's around sunrise
and sunset here. Sunrise is when most U.S. hams are asleep (around 11pm-1am
EST) and just getting to work when the sun sets. You also can't guess it
by looking out the window, since I'm closer to the equator, days are
shorter in the summer and longer in the winter.

I know the bands do open, on contest weekends, they suddenly "come alive".

The other problem is the bands themselves. Our 80m band goes to 3850 and while
legally 40m now goes to 7200, in practice, it stops at 7100 where the zillion
watt SWBC stations make ham communications impossible.

Quite simply, you can call "CQ DX" on 75m or 40m and no one this side of the
world will hear you and if we do and reply, you won't hear us unless you are
listening where we may transmit.

So skill, patience, and timing are as important as the bands being open,
and IMHO more important than how much power you use.

You will also find that if you tell people you are QRP, they often make
things easier for you, such as "CQ DX CQ DX DE (or "this is" for voice)
<callsign> QRP". Repeat your callsign several times slowly and
phoneticaly for voice and for CW don't call CQ faster than you the
slowest speed you want to copy.

You also should LISTEN for a while so you understand what the other operator
wants. If you want quick contacts for points or QSL cards, don't answer a CQ

or call someone who likes to chat and vice versa.

Since this is an antenna group, having a good low noise antenna in a low noise location helps. If all you hear is S9+ noise, you won't make many contacts.

Geoff.

An EM wave has an electric component and a magnetic component. The
antenna determines whether you are interacting with the electric portion
of the field or the magnetic. A shielded loop will receive the magnetic
portion of the field and ignore the electric if properly constructed.

How about in the mysterious too-good-to-be-true situation that it can?
Then what would happen?

I used to often play my Nintendo when it was connected to channel 3.
However, I was change the TV channel to 4. I could see the video of the

game but it was fuzzy and covered in grains. The music of the game was absent, and instead was filled with frightening-yet-enjoyable tones [sounding like a buzzer, lawn mower, or electric shaver] along with a faint audio of what was being discussed on the channel 4 news.

Is there a good chance I would hear something similar on my 2 GHz AM DX receiver in space?

Also, whenever there is drill or an actually emergency, the Emergency Alert System [EAS] plays their music. First they play the boring low-pitch square-wave tones. Then they play the high-pitched, terrifying, psychedelic sine-wave tones.

Is there a good chance I would hear something similar to the second higher-pitched set of EAS tones on my 2 GHz AM DX receiver in space?

Let me put you out of your misery,I do not know how old you are but
you unwittingly introduce a big no-no by postulating EM waves in space
and that implies a medium.

This is fine,they were faced with a dilemma in the mid19th century
inherited from Newton where they could live happily with the the Sun
influencing the Earth without a medium but could not conceive the Sun
illuminating the Earth without one.Check the top right column of the
following article from 1843 to affirm this -

http://www.bodley.ox.ac.uk/cgi-bin/ilej/image1.pl?item=page&seq=9&size=1&id=bm.1843.10.x.54.336.x.425

50 years later they dumped a medium on Newton anyway as 'absolute
space' and then conveniently rejected it all over again and then you
have 100 years of relativistic junk,some hopeless cases still think it
is an achievement but they are the ones who jump in here and try to
make you look like an idiot even though it may be a fair question.

Because a sine wave is a sine and you cannot
distiguish one from another. There is no
criterion that says anything is a "carrier"
and not just part of the background hiss.

> > it was one of those signals you just
> > eliminated.
>
> How so?

If you use a band pass filter at some frequency
that you guess could be a carrier followed by an
envelope detector, you get hiss. To eliminate
the hiss, you have to eliminate all other
frequencies so all you are left with is CW and
the envelope detector then gives a DC output.

Hi Jim

I haven't seen a simple answer to your question yet!

- I can see nothing in URL you sent to indicate that the radio has an internal antenna tuner. ATU's running to coaxial (SO239/M) connectors can be horribly lossy as well. (Or at least in the coax run from it to the antenna) If it had a tuner as a "feature" it would say so to enhance the products capabilities.

- If the antenna you are using presents a suitable load to the radio then you don't need a standalone tuner. I don't actually run a tuner, having built antennas that cover my bands of interest.

- If you want to have (say) just one simple antenna up, yes you'll need a tuner with this radio (or some other method to match things. Lots of possibilities to research here!)

- Keep in mind that with such a low output power the voltage handling specs of you tuning components are much lower. Very easy to throw one together with junk box parts.

Cheers Bob VK2YQA

They were only confused about the nature of the "ether".
Now we know that empty space is indeed not empty and
is something (as opposed to absolute nothing) that some
physicists describe as a "quantum soup" outside of which
EM waves cannot propagate.

I don't mind all the different answers. It actually helps me to figure out what it's all about.

I think my first misunderstanding about the Yaesu was that in reading the owner's manual, I had been expecting it to have a built-in automatic tuner (the Icom 703+ has one). When I read about the VHF antenna which comes with the radio it made it seem like I could use it on all bands.. of course I misunderstood what I was reading. I understand now that it does not have a built in tuner, and I would either have to use an external tuner or use a resonant antenna for whichever band I was going to use.

At any rate, if I go with the Yaesu, one benefit would be that I would gain experience in building and tuning my own antennas. That is something I am interested in. Having an automatic tuner might make me lazy. ;-)

I'm not worried about the low power either. I think having a high powered radio for my first rig would make me lazy. It would be easier for me to pump out wattage rather than fine tune my antenna. Besides that, when I am ready for higher power, I could add an amplifier. One thing at a time. ;-)

2062. High voltage and coupling from a vertical to adjacent coax

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-07 15:08:45 UTC
From: TF3KX <kristinn1@gmail.com>
Message-ID: <1191769725.761279.252680@50g2000hsm.googlegroups.com>
Source record: 35794

I am working on a topband vertical, approx. 12m/36ft tall, with four top hat wires sloping downwards, approx. 6m/18ft long each. Just about midway up this vertical I am contemplating mounting a dipole for the higher frequency bands, and running a coax from this dipole down along the vertical.

Now, I am worried about the interaction between the vertical antenna and this dipole coax. If I feed the vertical through an inductor at the base I presume there will be fairly high voltages on the entire vertical (I may run power up to a KW) and this may couple RF into the dipole coax, which in turn will give me RF where it ends, in the shack.

So, I would like your comments on:

a) Am I correct that there will be high RF voltages along the entire vertical, all the way from the "top end" of the base inductor?
b) What effects will these voltages have on the coax that runs along the vertical? High degree of RF coupling into the coax?
c) Would any kind of choke or filtering on the coax, on its way from the vertical into the shack, be efficient in removing this common-mode RF?
d) What if I move the inductor up the vertical, above the dipole? In that case all the high voltage will be above the dipole and instead I would have low voltage / high current below that inductor. Less coupling there?

Any comments would be appreciated.

73 - Kristinn, TF3KX

I just found this on the yaesu web site. They offer an antenna called
the ATAS-25. It appears to be an antenna that you can easily tune. The
instructions say to use the SWR meter (I think it has one built in) in
CW mode to test the antenna, and make adjustments to it as needed.

Unless you have experience with QRP, you might find this an exercise in
frustration. If you don't want to spend the money now, I would look for a
deal on a used 100W rig. There is not much to choose from in amplifiers
(other than VHF/UHF) that don't require 100W of drive.

yes to all your suspected problems. high voltages may arc over the
insulation of the coax, there will be very high induced currents on the
shield and the dipole, and in general it will be a mess. the worst part is
one you seem to have missed, with the coax running along side the vertical
it will be essentially like running a ground wire very close to the vertical
and will change it's impedance and likely cause all sorts of grief with it.

Most of the current solid state 100 watt HF rigs have a menu
adjustment that allows you to lower your power to the 5 or 10 watt
level, so you have a choice of power output, depending on band
conditions. With a QRP-only rig, you're stuck at that power level.
It's also a power level that works best in the CW or digital modes, as
opposed to SSB.

>along the vertical.

Hi Kristinn,

This may be the time to rethink both antennas. Hoist the dipole to the TOP of your vertical radiator and use IT for the top hat (after all, being lower will present proximity problems of the current top hat with the dipole). This, of course, will complicate things (like how to connect the dipole for dipole operation, and connect it for top hat operation).

>Now, I am worried about the interaction between the vertical antenna
>and this dipole coax. If I feed the vertical through an inductor at
>the base I presume there will be fairly high voltages on the entire
>vertical (I may run power up to a KW) and this may couple RF into the
>dipole coax, which in turn will give me RF where it ends, in the
>shack.

The solution (again, redesigning things) is to convert the vertical from base feed to gamma feed. This allows BOTH the vertical radiator and the dipole coax to be grounded at the bottom and to share the same current and voltage levels (and will solve half the top hat problem if you put the dipole at the top).

When both have the same potentials, there is no coupling between them - no high voltage problem except at the dipole feed point.

The solution here is to make the dipole one piece of wire connected at the middle to the top of the radiator (the top hat of the vertical), and to feed it with a small resonant loop. This will provide the voltage standoff to allow the coax to float near the vertical during its operation.

This is complex description in a short space, so I hope you can follow the outline of it and see the whole.

I Agree with Bob - I operate QRP when the mood strikes me and propagation is
good. I have a Kenwood TS-870SAT which is adjustable from 100 Watts down to
a little less than 5 Watts. Have worked DXCC QRP - 2/3 SSB, 1/3 CW, but this
was at the solar cycle peak.

Propagation is poor now because we are at the bottom of the solar cycle
URL:
http://www.dxlc.com/solar/solcycle.html

At the peak of the solar cycle one can work the world with 5 Watts (if
propagation is favorable) particularly on the upper bands - 10M thu 15M. The
next solar peak is around the year 2011

Building your own antenna for multiband is challenging. A G5RV comes to
mind - but usually requires an external tuner (even if your rig has an
internal tuner). Most modern rigs may cover a 3 to 1 mismatch and a G5RV can
be well out of that range on some bands.

Good Luck
Lamont

This gives me a new way of looking at the Isopole antennas. I am begining to think the upper sleeve is not there for isolation but rather it is a radiator and the bottom sleeve is there to decouple it from the mast and feedline.

>Any opinions would be helpful.

Hi Jim,

I think the confusion of needing no tuner is that you won't burn out
the finals driving a short or an open (you don't have enough power to
light a candle). Of course, this is no recommendation for a
successful QSO, but matching from the manufacturer's point of view is
about keeping your rig out of their repair shop (where they risk
having a mad customer for any of a number of reasons).

Second, automatic tuners in the bigger, 100W units, don't work all
that well with random wire. Ultimately you are building the SAME
resonant antenna for both rigs for the SAME reason = getting all the
power to radiate. Moral: build/buy an external tuner.

Third, as to power, learn all about electronics and build yourself a
100W linear. Cheaper than a 1KW linear and you may even find/rob a
100W amplifier deck from a dead HF rig at a swap meet. Their input is
typically in the 1 to 2 Watt range and this design (the deck) has been
around for three decades (which means if you steal ANY schematic from
the equipment from ANY manufacturer for the past 30 years, you stand a
good chance of having the complete design already done with a complete
and mud-ordinary parts list).

Again,the guys in the mid 19th century were inheriting a dilemma
Newton created when he rejected a medium.If you really have to believe
the cobblers of the last century where Albert rejects and aether by
attaching it to Newton's 'absolute space' then be my guest,it is an
incredible work of fiction but no more .

"The fictitious matter which is imagined as filling the whole of space
is of no use for explaining the phenomena of Nature, since the motions
of the planets and comets are better explained without it, by means of
gravity; and it has never yet been explained how this matter accounts
for gravity. The only thing which matter of this sort could do, would
be to interfere with and slow down the motions of those large
celestial bodies, and weaken the order of Nature; and in the
microscopic pores of bodies, it would put a stop to the vibrations of
their parts which their heat and all their active force consists in.
Further, since matter of this sort is not only completely useless, but
would actually interfere with the operations of Nature, and
weaken them, there is no solid reason why we should believe in any
such matter at all. Consequently, it is to be utterly rejected."
Optics 1704 Newton

So Cecil,if you read the article again and especially the top right
column you will see the distress of people who know they are stuck in
a rut but cannot find a way out of it.In the end they dumped aether on
Isaac as 'absolute space' and so began the relativistic junk. -

" In order to be able to look upon the rotation of the system, at
least formally, as something real, Newton objectivises space. Since he
classes his absolute space together with real things, for him rotation
relative to an absolute space is also something real. Newton might no
less well have called his absolute space ``Ether''; "Albert

Unless you have a severe reading disability,you will probably notice
Newton using explict terms like "utterly rejected" in regard to aether
hence the honest of the guys in the mid 19th century.

Hello,

I have no idea about NEC-4 output file format. Is there any samples
for looking into or documentation?
Thanks for any hints.

Regards,
Aziz

Most of my information comes from, "The History of
Modern Science". In any case, "empty" space within
the universe does have some sort of quantum structure
and EM waves indeed do require that quantum medium.
That's why light cannot escape the universe.

Jim

I agree with Tam. It is way more cost effective to buy a 2nd hand 100W radio than a new low power one. It's easy to reduce output power when you want to. The only reason I would go so low is if I ever wanted to run it backpack portable.

Compare some prices! You will then be able to afford an ATU as well!

Cheers Bob VK2YQA

Yeh, Larson makes an antenna that is designed for(insulated) vehicles
(thinkit is the "OS" series, 1/2 wave) , and also, it is possible to use
regular 1/4, and 5/8 wave antennas on such, useing Burglar alarm, or
"Waterproofing Repair Tape" (2 Inch aluminium tape), available at
Home Depot, or Lowes. Tho NOT at a 45 degree angle, should make a
adaquate counterpoise for your antenna, and can be on either side of
the roof! Give it a try! Jim NN7K

Thats it.. The upper cone is appx 5/8 wave and is the lower element.
The lower cone should be appx a 1/4 wave and is for decoupling the
line.

Okay. Sorry. "Carrier" is the wrong word. The radio reciever captures
and demodulated 2 GHz waves as if those waves are amplitude-modulated.
So this "carrier" is really the waves emitted from cosmic sources.

Wouldn't I hear sounds resulting from demodulating the 2 GHz waves in an
AM-manner?

2083. Ft-857d And ATAS 120a

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-08 01:38:15 UTC
From: maverrick <maverrickd@aol.com>
Message-ID: <1191807495.129971.30640@v3g2000hsg.googlegroups.com>
Source record: 35815

After having my vehicle broken into recently and my vhf/uhf radio stolen i decided to replace it with a FT-857D along with the ATAS 120a Antenna.
After reading lots of articals for and against the Atas i decided to purchase one for my self.
I installed the radio and atas but couldnt seem to get the atas to perform any low swr, the atas was fixed the the door side mount that my older aerial was but after checking it with a fluke meter i found that there was not a earth path from the mount to the suv body.
i solved this by fitted a seperate earth lead directly to the door pillar and mount, then i tried the atas again and what a difference,tuned in seconds even on the warc bands.

I managed to contact stations in zs,a,k,n and ve and most with good reports back to me owe and my location is GD so i have to say that for my first screwdriver type antenna it works well, the band i was using was 20m and 17m.
After a bit of playing Dx i tried 6m and managed to open a repeater 50 miles away and recieved good reports back.

The Ft-857D seems to work well as a mobile station.
I would like to here from anyone who as also used this combination and if they have moved away from the atas infavour of other types of screwdriver antennas.

You have some mind-bending implications there:

Such a quantum structure would not be coupled to the presence of matter. It would exist without mass.

The universe has discrete boundaries.

If EM waves reaching the boundary really do not escape and are not reflected (???) then the boundary is absorbing them and has a theoretical impedance of 377 ohms (same as what we innocently calculate for 'free space').

Alan,

I have suffered from birds (mainly Sulphur Crests) damaging coax.

For some years, I have been placing coax inside PE irrigation tube, and so far, have not sustained damage to cables protected in this way. The cockies have played around unwinding tape and breaking nylon ties, but they leave the irrigation tube alone.

It might work for you.

Not really, I havent had to build one in a long time and I just usually look up it up on the net. Next paln may be a 5/8ths with 30 degree sloping 5/8 'radials' with 1/4 radials or sleeve used to decouple the antenna from the feedline.

Jimmie

Exactly the same, except where you're looking for something that is done differently in NEC4 (e.g. NEC 4 supports catenaries, NEC2 doesn't, so the "readback" of the source deck is different)

But for things like near and far fields or segment currents, the format is the same.

It could be the dark energy thought to make up ~65%
of the universe and be responsible for the universal
expansion of "empty" space.

> The universe has discrete boundaries.

The volume of the universe could be *unbounded* and
finite, as is the surface area of the earth.

> If EM waves reaching the boundary really do not escape and are not reflected

One can travel forever on the finite surface of the
earth without ever reaching a boundary. Without changing
direction on the two-dimensional surface of a sphere, one
simply arrives back at one's starting point. (The East
Indies can be reached by going the opposite direction.)

One can probably travel forever within the volume of a
finite universe without ever reaching a boundary. One
might even arrive back at one's starting point while
traveling only in a "straight line".

Hi all,
I seem to recall a while back, someone posting an article about stopping birds - parrots in particular - from nibbling away at coax and insulated wires. One of our local club members has 4X10 on 2m and 4X15 on 432 MHz. We discovered that ALL of the 4:1 coax baluns had been chewed - some to the point that they were not connected to the yagis at all! Some of the baluns had sections completely missing. Amazingly enough, he still seemed to get out. Anyway, we have temporarily replaced the baluns but we need to find a way of preventing a reoccurrence of parrot pecking. All ideas and thoughts considered - sensible ones of course :)

I once thought that anyone believing the idea that the lament of light
leaving a star going to waste,hence 'warped space',was justing kidding
and did not really believe it but I have been proven wrong on that
count ,you people are quite serious about that insanity -

"This conception is in itself not very satisfactory. It is still less
satisfactory because it leads to the result that the light emitted by
the stars and also individual stars of the stellar system are
perpetually passing out into infinite space, never to return, and
without ever again coming into interaction with other objects of
nature. Such a finite material universe would be destined to become
gradually but systematically impoverished." Albert

http://www.bartleby.com/173/30.html

Again,I would fill you in with the details of how relativity protects Newton but you appear content with to believe you can set out and arrive back at the same place and indeed you can if you are an astrologer and liv in a 'warped space' predictive zodiacal framework

2096. Tweaking 80 meters on multi-band dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-08 17:01:56 UTC
From: "Bob D." <bobmgtd@insightbb.com>

Source record: 35828

I have a multi band dipole with traps/loading-coils. I would like to raise the resonate frequency of the 80 meter band by 200 KHz. Can I simply shorten the 80 meter part of the dipole by the proportionate part of 200 KHz?

I.E. - λ wavelength at 80 meters = 66.9 ft.

200KHz/3.5MHz = .057

66.9 ft x .057 = 3.8 ft.

If I shorten each leg of the 80 meter section of the dipole by 3.8 ft, will that raise the resonate frequency reasonably close to 200 KHz? (If this were a simple monoband dipole, I would not hesitate to lope off the 3.8 ft. But with the coils, I'm not sure what the effect will be.)

BTW, this is a Delta Alpha DX-LB plus. I realize shortening the 80 meter section will also affect 160 meters. This should not be a problem because I want to raise 160 also.

Heliax or semirigid coax might cause them to give up. Especially the latter.
75 Ohm stuff would be fine for the 4:1 balun, because you actually would
want it to be 100 Ohms.

However, we now know that it did indeed return as background
radiation. Therefore, space is probably finite and unbounded,
i.e. warped.

Albert also had a problem with "spooky action at a distance".

> Again,I would fill you in with the details of how relativity protects

Why do you say that "UHFs tend to the best for extremely long distance reception"? Have a look at the basic equation governing line-of-sight reception.

Why do you not answer your own question? It sounds to me like as reasonable a premise for a science fiction book as many that have been successful. You could perhaps spin it into quite an interesting story. You've already started with a premise that's so far from -- so very, very far from -- the current realities or even the dreams of people designing receivers that you may as well suppose you're going to receive whatever your wildest imagination might come up with. Since there is a nearly countless number of stars in the known universe, and since a large percentage of them could be planetary systems, each with the possibility of emitting interesting amplitude modulated carriers, your choices are pretty near limitless. Wow! Let your imagination run wild. It obviously did when you posed the question; you may as well let it run as wild with the answer. Back to you, Nonex!

Oh, and by the way, "spamming" comes, in one form, from posting too many places; I've trimmed off a whole bunch of groups for this reply. By my way of thinking, you're being pretty generous with yourself saying you don't spam.

Hi Bob,

By this parenthetical, it seems you already know this won't be easy.

Simple way to do this is loop back, say, 3 feet of wire and
electrially attach it to itself. This shortens the wire without
cutting it.

Update:

Now implemented also Radiation-Pattern-Division. It is working.

On most antenna calculations, there will be speed enhancements on multi-core / multi-processor systems with original windows-based NEC2 engines. But not for all antennas. It depends on many factors.

I achieved a seamless integration with fall backs, if there is no optimization possible. The generated (merged) output will be 100% compatible.

State now: Testing beta-version.
Coming State: Documentation and making on the web free (for private use) for download.

I hope, at the lastest one week there will be a first relase for download.

Birds attack Heliax at this location, but less so than vinyl covered
coax.

Sulphur crests are a particular problem:
http://en.wikipedia.org/wiki/Sulphur-crested_Cockatoo

Nevertheless, Heliax is pretty much unaffected as they usually rip small
holes in the vinyl sheath which doesn't affect the cable due to the solid
external conductor, and even when they punch through the copper shield,
water will not soak throught the cable due to the closed cell foam that
is bonded to the shield with adhesive.

There might be more creative solutions Alan. I stopped feeding birds when
Sulphur Crests starting congretating en-masse and before they started
eating the house.

How can it get any easier than what I described in my article about the 2x4 based 1/2 wave J-Pole with the unconnected 1/4 wave matching stub placed 4" from the 1/2 wave radiator? You slide the alligator clips up and down the two elements until the SWR matches, then you're finished.

Of course, building a similar antenna for outdoor use will require some experimentation, but it shouldn't be that difficult to accomplish. The performance was just fine as far as I was concerned, working distant 30 mile away repeaters with ten watts or less from INSIDE the house (steel siding - no less) and obtaining full quieting on the repeater.

2104. Antenna for receiving WWV/10MHz: am I asking too much?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-09 02:16:37 UTC
From: Frnak McKenney <frnak@far.from.the.madding.crowd.com>
Message-ID: <13glp45ltevoce4@corp.supernews.com>
Source record: 35836

I'm in Richmond, Virginia and I'm trying to noticeably improve my reception of WWV's 10MHz signal from Fort Collins, Colorado. It all seemed so simple, two weeks ago: wind some wire, solder a connector, and Hey...presto! a clean WWV signal. <grin!>

It wasn't so simple, and I'm afraid I've let it become an "ego thing" (see also: resource sink). I've outlined the problem below in the hope that someone can either suggest something I haven't already tried, or even point out something really dumb that I've been doing and shouldn't keep doing. <grin!>

Background

Several years back I inherited a Heathkit GCW-1001 Most Accurate Clock II from my father. This is an update to it's predecessor, Heath's GC-1000 Most Accurate Clock; its circuit, built around a Philips TDA1072A AM receiver IC and an 87C52 microprocessor, monitors WWV's 10MHz signal and decodes the BCD-coded 100Hz subcarrier (details at http://tf.nist.gov/stations/wwv.html) to keep the MAC-II accurate.

This MAC-II worked fine for my father: he had a 30 meter dipole of some kind in the attic, above the second floor of a house on a hill. For him, WWV's 10MHz signal from Fort Collins came in regular as... well, "clockwork". <igg!>

For me, in a one-story-plus-basement, in a low spot in a river valley, it's a different story. The GCW-1001 has a stack-o-LEDs signal strength indicator driven by the TDA1072's AGC output; it would wander between 2 and 4 LEDs with my 40" indoor dangling wire antenna, and it could take weeks or months for atmospheric conditions to randomly improve the signal to where the GCW-1001 could "lock in" a time.

Two weeks ago, in a fit of madness, I decided to try building a better antenna, one which would let the clock lock onto WWV at least, say, once a week. The tuned-loop antenna I've built _has_ increased the signal -- I'm seeing 4-5 LEDs lit on a regular basis, and 6 on occasion -- but the clock still isn't sync'ing to WWV's time signal. The clock face remains at a cute(?) 7-segment "not SEt" display. And what seems to be louder is the carrier -- or _a_ carrier, at any rate -- but not the tones or the human voice time callout coming out of the GCW-1001's speaker.

I seem to be up to my assets in alligators, and the swamp doesn't seem to be draining much.

Problem

My main problem is that, although the GCW-1001's LED "Signal" stack _says_ it's getting a stronger signal, what I hear through the speaker monitor isn't _clearer_. There are long periods when I cannot hear any WWV tones through the GC-1001's speaker, the tones/ticks are faint even when there are 5-6 LEDs lit, and the voice is almost never audible/distinguishable. The clock _seems_ to be sync-ing a little more often (it's done it four times in the past two weeks), but I had hoped it might happen a _little_ more frequently.

Am I asking too much? Is WWV's 10MHz signal from (say) 2,000 miles away, simply too weak to pick up solidly without an outdoor antenna?

What I've tried

My (second) attempt at a 30m indoor loop antenna:

Main loop (tuned): A 36" near-circle of #12 insulated house wire with an AM/FM tuning capacitor across it.

Pickup loop: One (36") turn of #27 magnet wire taped to the #12 loop with electrical tape<grin!>. The ends (scraped and tinned) are tied to the GCW-1001's 50ohm antenna input with a couple of 12" clip leads and a 3' section of coax.

The loops are mounted on (and held in shape by) a 1'x4'x0.5" "backboard" made of "blue foam" house insulation that I found in my basement; the loops are held in place by small plastic cable ties. The foam backing is resting against a (roughly) N-S wall, which _should_ orient the loop plane across the WWV wavefront for maximum pickup.

Does this sound like a reasonable attempt at a tuned 10MHz loop?

Is there any reason to believe that the foam backing would affect the loop inductance? I'm assuming it's a good insulator and nothing more, but that's an assumption.

Is it possible that I'm picking up a non-WWV dignal so strong that it's masking WWV? I tried tuning around 10MHz with a shortwave radio; it didn't find WWV -- not a particularly hopeful sign -- but it did pick up a station called (IIRC) WWCR. WWCR's 'web site (www.wwcr.com) lists its transmitter #4 as using 9.985MHz and 9.975MHz between 0900 and 2100 CST.

Any advice or suggestions will be appreciated, up to and including "You can't power a hedge trimmer from two AAA cells!".

Thanks...

Sounds like it's being masked by some type of noise,
but this could just be from the signal being very weak.
If you can hear other stations ok, it probably the propagation
more than anything. Being that you can barely hear it on a
regular receiver seems to bear this out.
Unless a noise is local, and you are trying to null it, I see no
real advantage to using a small loop vs whatever else.
I would make sure you don't have any local noise. IE:
powerline noise, etc. If you did, the loop would be a good
antenna to null that noise as long as you can turn it.
But if there is no local noise, and the noise you hear is
atmospheric, then it's not going to matter much what
you use.
I've got a hunch that the propagation is just the pits for
you right now.
I wouldn't be surprised if you tried it in a couple of months
and it worked ok.. If you hear it on the regular radio ok,
the clock should too. If you can't hear it on the regular
radio, the clock probably won't either, and there is
probably not much you can do about it.
There should be times that it comes in fairly decent though,
depending on time of day, etc..
I would use what you hear on the regular receiver as to
whether the signal is really there or not.
Propagation on most of the HF bands has been fairly
flaky the last few months. IE: I got on 40m in the daytime
the last time I was in OK, and it was like I was on 20m..
Band was real stretched out, and pretty long skip zones.
I'd miss the semi locals I'd usually talk to, and end up
hearing stations 1000 miles away instead.

2106. RFI Question for HF mobile

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-09 14:19:26 UTC
From: Michael Coslo <mjc5@psu.edu>
Message-ID: <feg2llfgg1@f04n12.cac.psu.edu>
Source record: 35840

In my HF mobile setup - a legal limit sized Bugcatcher on a 04 Suzuki Vitara - I have some significant RFI coming from my ECM module. Starts as soon as the ignition key is turned on - the engine doesn't need to be running.

I've gone through the usual things for mobile installation, like bonding the doors, exhaust system, frame, radiator and hood. Nothing on the fuel pump, as I 'd have to remove the tank to get at it. Only makes a small thwip upon starting, so isn't a big problem.

The ECM was verified by a small radio held at various places on the vehicle.

Any ideas? I did put some ferrites on the ECM wires. It helped some.

G'Day Owen,

Looks like a good idea. I'm not sure what cockies they were - this
was at the QTH of VK2ZRE. I don't get galahs here and I don't have a
problem so it might be them. They had chewed up any PVC tape as well.
Oddly enough, they hadn't done much to the RG213 which are the main
feeders but the baluns are RG58 and appear to be of a softer covering.
Perhaps that's why they went for it - easier to chew :)
Anyway, I'll be back there tomorrow so will see if Ros has any PE tube
about. Being a "cockie" I'm sure he will have.

Cheers,
Alan

100 ohms? This is just a half-wave coax balun. All the books say it
should be 50 ohms - same as the feed and the yagi. The only place where
a different Zo is used is where the four yagis combine. There, a
quarterwave section of TL of Zo=25 is used to match the 12.5 ohms of the
four yagis in parallel to the 50 ohm main feeder.
The main feeder is heliax so the birds haven't got to that - yet. (Tough
birds down here in VK!!)

How would this be significantly different from having 1/4 wl radials,
feedpoint, 5/8ths element, phasing section, 5/8th section?

Jimmie

It is a 200 Ohm antenna. Each half is 100 Ohms to ground.When you put the 2
sides together you get 50 Ohms. Since the line is 1/2 wave long, any
impedance will work, including 50. CushCraft made a beta match 6 meter beam
which used a 1/2 wave section of RG11 75 Ohm coax. People have also use 93
Ohm coax, but its loss at 1:1 SWR is probably more than RG8 at 2:1 .

Even with my antennas on a 150 foot tower there are times of day when WWV at 10 megacycles is not audible... This is just the way the daily propagation cycle is at 30 meters.
My best advice is to put up a dipole for 30 meters, even if you have to bend the ends to make it fit your space... A horizontal dipole being balanced picks up less vertically polarized noise than vertical antennas... Getting the wire outdoors will help also... You are likely picking up lots of humm and buzz inside the building from various electrical and electronic devices...

The other issue is whether your clock is actually able to synch with the WWV signal... You may have a defect in the clock... It would seem that 4 or 5 bars should have done the trick...

You are very 'special' people at least those who traffic in relativity
and other such exotic junk. and I am a little surprised people have
not outgrown the excesses of the last century a lot sooner and a
little quicker when faced with the fiction but then again you are
unfamiliar with most of the srguments anyway.

SAGR." I know; such men do not deduce their conclusion from its
premises or establish it by reason, but they accommodate (I should
have said discommode and distort) the premises and reasons to a
conclusion which for them is already established and nailed down. No
good can come of dealing with such people, especially to the extent
that their company may be not only unpleasant but dangerous."

Dialogue Concerning the Two Chief World Systems, 1632 Galileo

For what it is worth,Newton created his own idiosyncratic astronomical outlook and relativity is merely the symptoms of that late 17th century disease,again,a very astrological one.Somehow people know that the garbage of the last century is just that but for the present it relies mostly on what Galileo correctly identifies as both unpleasent and dangerous.

Good luck to you and your 'warped space' colleagues.

Ive had my Dipole tween two trees for years now. Next door always
been rented and Mine has been there since the previous Owner let me
hang it up there. Well the recent renters Hacked the cord. And I
dont know the current owner. So I must do somthing in my yard.
Except I can only go into one corner and it slopes pretty quick down
about 8 feet at the end.

I can come up the fence about 15 feet to gain it back.

But what im looking for is a cheap way to hang the dipole end back up.

I have some room on the other tree to pull it back to make up the 15
feet I'd lose that way.

Thanks
Scotty W7PSK.

2118. Re: NEC-4 output file format questions?

Hello Arie,

before be confronted with unseen and unexpected data, I will support
on the first version only "NEC-2D" output files.

NEC2 Engine Booster is finished now. Everybody will be impressed about
the performance, that can be taken from multi-core / multi-processor
enhancements.
I have started the documentation for the web.

On the coming version, I will support near-field (NH, NE-cards) data
too. And when I can get a NEC-4 engine for evaluating and testing,
than it will also support NEC-4 engines.

Thanks everybody for the help.
Greetings,
Aziz

That's good!

Polarization was one of my thoughts.

Also, how is the synch tone derived by the receiver? Maybe that part of the radio needs tweaking? One would think that seven segments out of ten should be sufficient. I'm assuming there are ten segments total.

Actually, I disagree in part with all the theories.
I think the universe is finite and unbounded and
even though expanding at the present time, will
eventually collapse on itself into a Big Crunch.
I believe the expansion is mostly an illusion that
goes undetected because of relativity and dark
energy-matter effects.

> Good luck to you and your 'warped space' colleagues.

How do you explain a gravitational lens without
space being warped by a galaxy?

Since he said previously that he could hardly hear the tones/voice, isn't it probable that the receiver is just seeing mostly noise?

As mentioned by someone else, propagation is currently "very ordinary" (aka poor) at present, so maybe he's just out of range.

I am in New Jersey. Propagation from Colorado to here is probably similar to Virginia.
This morning, Tues, 10/9, I listened to WWV on 10 MHz with the 4 antennas I have at my disposal to see what kind of signal level I get.
My antennas are 80 meter and 40 meter dipoles, a 20 meter yagi and a 30 meter dipole, all at about 50 feet.
On the first 3 antennas WWV runs about S6-9, and on the 30 meter dipole it is 10-20 db over 9.
This evening, 6 pm, the first 3 antennas haul WWV in at S9 and the 30 m dipole has it at a rock solid 30 over.
So I agree with the advice you got to string up some kind of dipole and throw out that loop, there is plenty of signal, you just have to go get it.

Rick K2XT

Frank, can't you erect anything outside at all? A 10 metre dipole, is after all, only about 5 metres long. And if you can't do that, what kind of attic do you have? If your house is oriented correctly, you could even build a three element wire yagi pointed west inside the attic. Dimensions shouldn't be that critical for receive only, and space the elements at about 2.5 metres. Basically one element at about 47 feet, one at about 49.3 feet, and one at about 45 feet. Split the 47 ft one into two, feed it directly with 50 ohm coax, one side to the shield, one to the centre conductor, and you have a three element wire beam pointed, hopefully, west. (Put the longest element on the east side, the shortest on the west.)

Use the longest 2 X 4s or 2 X 6s you can find, and make an an A frame out of them, with the bottom 2 to 3 ft wide. Bolt them to some stakes driven into the ground next to the fence, and then stand up the A frame against the fence. With luck, you should be able to get 20 ft or more, even if you need to bolt a couple of 2 X 4s together to lengthen them.

Otherwise, you could do the same thing with an aluminum house ladder that goes up to 30 or 40 ft, and use it to tie the antenna to.

Just a week ago I took down a 40 foot high 2 X 4 wood (untreated Douglas fir) A-frame I've had up for about 30 years. It hasn't had any maintenance except for a couple of coats of deck stain. It finally developed enough rot at points where it was nailed and bolted that it had to come down. The A-frame was built according to the design which has been in the ARRL Antenna Book for decades. It's still there -- look for "A-frame mast" in the index. I once made a slightly shorter one with 2 X 3 lumber. It was a lot lighter and easier to handle, and plenty strong. Even 2 X 2s would be ok for moderate height, if you can find some reasonably clear pieces. If you're going to be supporting it with something like a fence, you'll need to keep the weight to quite a bit less than my 40 foot 2 X 4 version. Lower height, smaller dimension lumber, a lighter type of wood, or some combination should get you something usable.

Sigh. So... there isn't some kind of cubist-wire-sculpture shape I
can bend my antenna into and magically make WWV appear? <grin!>

>Unless a noise is local, and you are trying to null it, I see no
>real advantage to using a small loop vs whatever else.

I constrained the problem by insisting on "indoor" and "small".
From your feedback, and my experience, it looks like I won't get
much further unless/until I'm willing to relax one of my
constraints.

>I would make sure you don't have any local noise. IE:
>powerline noise, etc. If you did, the loop would be a good
>antenna to null that noise as long as you can turn it.
>But if there is no local noise, and the noise you hear is
>atmospheric, then it's not going to matter much what
>you use.

I built a long-wire "antenna" last evening and I _thought_ my signal
picked up a bit... for a little while, anyway. I took a 100'
extension cord and unreeled it from the west end of the house to the
east end where the MAC-II is set up. On the floor. (Hardly a
"phased array"<grin!>, but I wanted to try _something_.)

I put the (plastic) reel with the rest of the cord up about a foot away from my "loop", and I did seem to get a stronger signal (translation: on the fade-ins it sounded a bit louder). I could hear the "notes" fairly well at times and I could _almost_ make out what was being said in the the voice segment. On the other hand, this was somewhere around 1800, give or take an hour, and the signal was fading in and out... it could have simply been due to atmospheric conditions.

One good thing I learned was that I may have been tuning my antenna incorrectly. It seems that there is a "roaring" that peaks the GCW-1001's LED stack, but when I can distinguish the WWV tones and maximize their loudness through the speaker I'm slightly _below_ that "roaring". In other words, I _have_ been mis-tuning, and inadvertently helping drown WWV's signal out. Ouch. Wish I had an accurate 10MHz signal generator; what I have is intended for audio work and limited to about 1.5MHz.

>I've got a hunch that the propagation is just the pits for
>you right now.

Well, that's certainly a true description of what I'm experiencing <grin!>, but I've had the MAC-II since 2004 and suffered the same poor lock-in, and a MAC-I (GC-1000) a decade (ack!) behaved similarly. 'Course, I used its built-in whip (something the MAC-II lacks); I didn't build _it_ an antenna of its very own. <grin!>

>I wouldn't be surprised if you tried it in a couple of months
>and it worked ok.. If you hear it on the regular radio ok,
>the clock should too. If you can't hear it on the regular
>radio, the clock probably won't either, and there is
>probably not much you can do about it.

I was afraid of that. I suppose I could build a battery-powered RF amplifier and stick it on the antenna, but the trick (stop me if you've heard this one <grin!>) is to make just-the-stuff-I-want louder. Making _everything_ louder doesn't help me.

>There should be times that it comes in fairly decent though,
>depending on time of day, etc..
>I would use what you hear on the regular receiver as to
>whether the signal is really there or not.

You're probably right. Means I have to clear off some more lab bench space next to the MAC-II, and I should probably re-tighten the dial cord on the Mohican and dust off its tuning capacitor plates. <grin!>

This may wind up being a classic example of the "DIY->DYI Transformation": a "really neat" do-it-yourself idea which started out simply enough, but which has somehow turned into a must-complete, spare-no-expenses Do-Yourself-In Project. <grin?>

>Propagation on most of the HF bands has been fairly
>flaky the last few months. IE: I got on 40m in the daytime
>the last time I was in OK, and it was like I was on 20m..
>Band was real stretched out, and pretty long skip zones.
>I'd miss the semi locals I'd usually talk to, and end up
>hearing stations 1000 miles away instead.

So... if I ran this really long piece of coax out to Oklahoma, then I could pick up Fort Collins really well via skip? I've got a bunch of A/V 75ohm stuff, and some old T-Base2 Ethernet cables; that's a start... (Riiiight! <grin!>)

I think it's time to step back and think about what I've discovered and learn a bit more theory; my ARRL Antenna Handbook (1991ed) arrived in yesterday's mail, so I'll be learning from The Source. (I sent my brother Bruce an e-mail message a few days back explaining why antenna length mattered; it made sense at the time, but I may have to revise it after some more reading.)

And, if I decide I need a radio-based time source before I can get a good WWV signal, I could always hack a WWVB clock -- as long as it had a dead LCD panel or something: I have this weird reluctance to tear apart anything that is still working. <grin!>

Assuming, of course, that I can pick up WWV_B_ here. <grin?>

Anyway, thanks for reassuring me that my poor WWV reception really might not be due to a poor antenna design. If I ever come up with a Really Good Solution I'll post back here.

What would help you is an outdoor active antenna. For a start look at MFJ's.
It's a metal box with an amplifier in it, and a whip antenna. It uses a
small box at the receiver end to pass DC up the coax to power it.

Placing it outside would help. Placing it outside and away from noise
sources, or on the roof would help more. A whip antenna is used because
it's a cheap commerical off-the-shelf (COTS) item. It could be replaced
with a thin wire. The coax could be replaced with a run of (more expensive)
mini-coax. This would make it easier to hide and you may be able to use it.

If you are handy with building things, there are lots of designs for similar
devices, the easiest is a single MMIC type amplfier. It may be more difficult
to actually do as they are very sensitive to static.

If all you have is a window, a loop around it would do. If it has a metal frame,
and all 4 sides are connected to each other, you can try using it as a loop.
If not, thin wire held up by transparent tape, or that metal tape used by
alarm systems would work.

Geoff.

Yup, the experts were not experts after all just phony's.
Ofcourse we now have to wait for comments like " I knew that all the
time",
"I have been using that method for years", "that was invented by
Mantovani
a hundred yeard ago but he just didn't get around to printing it"
Art

To borrow from Galileo again -

SALV. "The same thing has struck me even more forcibly than you. I
have heard such things put forth as I should blush to repeat--not so
much to avoid discrediting their authors (whose names could always be
withheld) as to refrain from detracting so greatly from the honor of
the human race. In the long run my observations have convinced me that
some men, reasoning preposterously, first establish some conclusion In
their minds which, either because of its being their own or because of
their having received it from some person who has their entire
confidence, impresses them so deeply that one finds it impossible ever
to get it out of their heads. Such arguments in support of their fixed
idea as they hit upon themselves or hear set forth by others, no
matter how simple and stupid these may be, gain their instant
acceptance and applause. On the other hand whatever is brought forward
against it, however ingenious and conclusive, they receive with
disdain or with hot rage--if indeed it does not make them ill. Beside
themselves with passion, some of them would not be backward even about
scheming to suppress and silence their adversaries. I have had some
experience of this myself."
Dialogue Concerning the Two Chief World Systems

It is many years now since I dealt with relativity or rather the
people who are proponents and opponents of that exotic

junk,occasionally I will join a thread but even then only as a cameo appearance.When I looked at Albert's explanation for 'warping space' based on the lament that light leaving stars was going to waste I thought it was hilarious and still do but nothing could have prepared me for his rejection of the idea of stellar islands -

"This view is not in harmony with the theory of Newton. The latter theory rather requires that the universe should have a kind of centre in which the density of the stars is a maximum, and that as we proceed outwards from this centre the group-density of the stars should diminish, until finally, at great distances, it is succeeded by an infinite region of emptiness. The stellar universe ought to be a finite island in the infinite ocean of space."

http://www.bartleby.com/173/30.html

In 1925 ,five years after he wrote that conclusion,these things showed up -

http://web.mit.edu/kayla/Public/Backgrounds/Space%20-%20Andromeda%20Galaxy.jpeg

Look,I have no axe to grind and if you wish to believe the cobblers of the last century then fair play to you,two thumbs up and whatever other accolade I can throw in your direction,I find the whole thing funny but that is just me.

<frnak@far.from.the.madding.crowd.com> wrote:

>Am I asking too much?

Hi Frnak,

Judging by the questions and responses, I would have to say "Yes."

To this point you haven't exactly demonstrated you have a problem,
just a complaint of a signal of poor quality to a human's perception.
For the clock itself, that complaint is arguably weak.

Let's just examine the evidence for the problem: There is none!

You have a clock that has 100mS resolution, and yet you have never
said how much it is off. 100mS? 1S? 10S? 1 minute? 1 Hour? All,
or any part of any of these metrics?

As Reggie would have chimed in at this point "If you can't measure it
and express it with a quantifiable, then you don't know anything."

Of course, your only source of accurate information is the one you are
suggesting has a problem. It probably doesn't have a problem, but
then how does one use this source's accuracy to check itself? You
would need a second clock to check it, and we would be hearing your
complaint in stereo.

I've calibrated time standards to the nearest 100nS and it is
accomplished at one sitting, no need for total connectivity such as
you might imagine (unless the clock you have is especially crappy).

Your clock has a resolution of 0.1 second. There are roughly 1
million ticks of the display in a day. A simple XTAL oscillator at 10
MHz would exhibit 50ppm stability and in a day wander up to 0.5
second. The next day it might wander back, the day following it might
slip below by 0.5 second. You would be hard pressed to confirm this
with over the air matching to the strike of the WWV gong - except if
the clock is especially crappy (and it could be). The same XTAL might
also exhibit an absolute error of 50ppm and accumulate time error.
This would be far more noticeable over the course of a week (you could
confirm the error by listening to time announcements - but you have
been silent to this issue).

These worst case errors all presume that the internal circuitry cannot
over the course of 24 hours manage to pull out one of 1400
synchronizing opportunities to phase lock out the error. These
circuits are generally optimized to accomplish just this (they work

fine in watches with a 60KHz signal after all). Your clock may be especially crappy (but that is unlikely).

The clock synchronizing circuits don't have to listen to the bandwidth of noise you hear, the speaker is for your convenience, not the clock's. I am sure that it works fine with only 1 LED lit - this is not a case of "can you hear me now?"

> It is a 200 Ohm antenna.
So it is. Anyway, the question arose as I'd never seen anything other than 50 ohms used for the balun.
Anyway, I spent all day on the 8 baluns (4 for 432 MHz and 4 for 144 MHz) and did as Owen suggested - put 1" PE irrigation pipe over the baluns. Let's see the little so-and-sos eat through that!!

I'm not sure how cheap you wish to stay, but I would suggest a couple 10' stackable sections of 1"dia steel masts as often available at hardwware stores' TV sections. (I think some Radio Shacks carry them, too, but haven't see the 10' ones in some time there.) They are strong, light, and I don't think they cost that much. Certainly easier to work with than wood, will have less visual impact, and will probably put much less strain on the fence post where you mount it.

The patent, US 7187335, is a real hoot. I especially like the part where he describes doubling the bandwidth by adding a parasitic winding intertwined with the base coil helix.

Do you suppose his antenna is in equilibrium? Could proper application of Artsian-Gaussian theory improve it even more?

In the USA, Home Depot (and presumably Lowe's, etc.) sells 10- to 20-foot
lengths of pipe for the top "rail" of chain-link fences. Sometimes it
even has the swaging that allows one to fit in the end of another.
Remember that all such pipe masts will need guying.

> reception.

Lower frequencies are absorbed by charged particles. Ionized zones [such as Earth ionosphere and the heliosphere around the solar system] tend to block low-frequency radio waves. That is why UHF is the best.

UHFs are the ï¿½sweet-spotï¿½ of radio waves. They are high-frequency-enough not to be attenuated by objects that block longer-wave radio signals and low-frequency-enough not to be attenuated by objects that block infrared rays.

Okay, I will let my imagination run wild.

I would hear scary stuff on the space stationï¿½s radio.

I used to often play my Nintendo when it was connected to channel 3. However, I was change the TV channel to 4. I could see the video of the game but it was fuzzy and covered in grains. The music of the game was absent, and instead was filled with frightening-yet-enjoyable tones [sounding like a buzzer, lawn mower, or electric shaver] along with a faint audio of what was being discussed on the channel 4 news.

I would hear something similar on my 2 GHz AM DX receiver in space.

Also, whenever there is drill or an actually emergency, the Emergency Alert System [EAS] plays their music. First they play the boring low-pitch square-wave tones. Then they play the high-pitched,

terrifying, enjoyable, psychedelic sine-wave tones.

I would also hear something similar to the second higher-pitched set of EAS tones on my 2 GHz AM DX receiver in space but not the 1st lower pitched tones. The lower-pitched 1st tones donï¿½t at all resemble what I would hear on the AM receiver.

In addition, I would hear sounds that are similar to the following terrifying-yet-enjoyable tones present on this keyboardï¿½s 100 sound tone back:

http://concertmate.evenement0.net/img/concertmate_realistic_concertmate-450_img1.jpg

#75 ï¿½cosmic soundï¿½ when the volume is at maximum

#76 ï¿½telephoneï¿½ when the volume is at minimum and I press keys from the 7th black key [from the left] or lower. If any key that is right of the 7th black key is pressed, the sound is totally different and will not even remotely resemble anything I would hear on the AM receiver.

#81 ï¿½marimbaï¿½ when the volume is at minimum and I press the lowest or highest key separately ï¿½ especially if I first press the lowest key, then let go, and then immediately press the highest key afterwards.

#85 ï¿½afro percussionï¿½ when the volume is at maximum and I smoothly slide my hand from lowest to highest note and then highest to lowest note or if I play notes two or more notes with one no higher than the 7th black key from the left and the other note no lower than the 10th key from the right. Actually any combinations of this tone will resemble what I would hear on my 2 GHz receiver.

#96 ï¿½bass/pianoï¿½ when the volume is at maximum and I press the lowest key.

All the sounds I hear on the receiver are those that result from the radio waves emitted by the magnetic fields of objects in the distant cosmos -- such as magnetars. At times, when the magnetic objects cause magnetic vibrations at an RF-rate, they cause radio waves to be generated. If the rates include 2-billions-vibrations-per-second, then my receiver will demodulate the 2 GHz parts and I can hear the signals -- provided that the demodulations result in frequencies anywhere from 20 to 20,000 Hz [the human hearing range].

Of course, they are designed to be used with steel
pile-driven fence posts so I drilled holes and used
large UV-resistant tie-wraps to attach them to the
tower sections. It worked well.

Jim,

near-field data and NH/NE cards will be anyway not yet supported
(optimized) at the moment. I looked into the data records and found,
that they would be acceptable to my smart parser and it would not
cause any problems.
But I found another items on NEC-4 output data, that could cause
unpredictable results. These differencies have to be implemented and
could support on the next version of NEC Engine Booster.

Thanks for your help,
Aziz

I have read that wonderful sci-fi novel from the 19th century -

"'Scientific people,' proceeded the Time Traveller, after the pause
required for the proper assimilation of this, 'know very well that
Time is only a kind of Space. "

http://www.bartleby.com/1000/1.html

So,you believe in a 1905 relativistic concept whoes conclusions match
those which could be found in any sci-fi bookshelf in 1898 !.I suppose
you cannot make the correlation between the dates of 1898 and 1905 but
then again,no person should need to.

So Cecil,go enjoy the epilogue of Well's fictional 'Time Machine'
novel,close the book and don't go believing in the flatlanders of
Albert except as an uproarious formal extension of the narrative -

http://www.bartleby.com/173/31.html

Maybe you would like to base geology on Verne's 'Journey To The
Center Of The Earth' but I think you at least know by now where I
stand and I leave you to your own devices.

I've been looking to *up* my ham radio experience by constructing a few projects. Though I have a few toys already, (Spec analyzer, sweep gen scope) I've been looking at purchasing an RF analyzer. I am looking for something that can easily scope out resonant circuits, antennas and measure impedance and reactance.

The MFJ series seems dominate in the market but does not cover all the freq ranges I'm interested in. I've found a company called Autek Research who seems to make a few continuous analyzers but find very little about them on google.

Are there any other companies making RF analyzers?

Is there something that MFJ has that others lack?

Is Autek Research OK?

I Thank You in advance!

> Time is only a kind of Space. "

I agree. I think time, like universal expansion,
is an illusion akin to a religion. I tend to agree
with Julian Barbour in, "The End Of Time".

What we experience as a "passing-of-time event",
is only a change whose probability function has
collapsed. The past is *where* (not when) all
probability functions have collapsed. The future
is *where* (not when) no probability functions have
collapsed. Time, after all, is only a physical
dimensional *change* in the rotation of the earth
and/or in earth's orbit around the sun.

IMO, time is no more real than the Sun-God riding
his chariot across the sky every day. Any equation
that contains a time term needs to take that into
account.

> account.

Of course this is all true. However, to primitive earthlings viewing the daily progress of the sun across the sky the chariot theory is perfectly sane and real. That IS how it appears to the earth observer. Same for time.

For argument assume that all possible events and actions and the progression between them all is laid out in some huge matrix. In that sense all this structure is only "a kind of space". Now imagine a consciousness that has a certain velocity and is capable of experiencing the matrix in a very narrow viewpoint much as a needle plays a phonograph record. That needle has followed a certain path up to the point where it presently is. That path is fixed and unalterable. What it did, it did! Where the needle is right now is in fact, experienced as 'now". But the path that the needle might take is open to choice (free will) and that new path would be termed the future. The needle doesn't skip around so choices DO have consequences of things you must "go through" if you choose a certain "path".

If you take flatland to the next level, what you observe is that higher dimensions manifest themselves in the lower dimensions as time! So if you were to take a viewpoint high above the matrix observing a consciousness inscribing it's path through life, to you you'd see all "parallel universes" plus the past that was taken, plus what was being experienced "now" as well as the possible choices for the future. Given some input, you probably could even estimate the most probable future path to be chosen.

But of course none of this answers the most important question which is what do 2 GHz AM signals in space sound like? I believe the answer is that they sound just like the Venusian signals Adamski received from the beamships right before they appeared!

> reception"? Have a look at the basic equation governing line-of-sight
> reception.

Lower frequencies are absorbed by charged particles. Ionized zones [such
as Earth ionosphere and the heliosphere around the solar system] tend to
block low-frequency radio waves. That is why UHF is the best.

UHFs are the ï¿½sweet-spotï¿½ of radio waves. They are high-frequency-enough
not to be attenuated by objects that block longer-wave radio signals yet
low-frequency-enough not to be attenuated by objects that block SHFs [3
GHz to 30 GHz range], EHFs [30 GHz to 300 GHz range], THz-radiation, or IR.

> you, Nonex!

Okay, I will let my imagination run wild.

I would hear scary stuff on the space stationï¿½s radio.

I used to often play my Nintendo when it was connected to channel 3.
However, I was change the TV channel to 4. I could see the video of the
game but it was fuzzy and covered in grains. The music of the game was
absent, and instead was filled with frightening-yet-enjoyable tones
[sounding like a buzzer, lawn mower, or electric shaver] along with a
faint audio of what was being discussed on the channel 4 news.

I would hear something similar on my 2 GHz AM DX receiver in space.
Obviously excluding the "channel 4 news" part.

Also, whenever there is drill or an actually emergency, the Emergency
Alert System [EAS] plays their music. First they play the boring
low-pitch square-wave tones. Then they play the high-pitched,
terrifying, enjoyable, psychedelic sine-wave tones.

I would also hear something similar to the second higher-pitched set of
EAS tones on my 2 GHz AM DX receiver in space but not the 1st lower
pitched tones. The lower-pitched 1st tones donï¿½t at all resemble what I
would hear on the AM receiver.

In addition, I would hear sounds that are similar to the following
terrifying-yet-enjoyable tones present on this keyboardï¿½s 100 sound tone
back:

http://concertmate.evenement0.net/img/concertmate_realistic_concertmate-450_img1.jpg

#75 ï¿½cosmic soundï¿½ when the volume is at maximum

#76 ï¿½telephoneï¿½ when the volume is at minimum and I press keys from the
7th black key [from the left] or lower. If any key that is right of the
7th black key is pressed, the sound is totally different and will not
even remotely resemble anything I would hear on the AM receiver.

#81 ï¿½marimbaï¿½ when the volume is at minimum and I press the lowest or
highest key separately ï¿½ especially if I first press the lowest key,
then let go, and then immediately press the highest key afterwards.

#85 ï¿½afro percussionï¿½ when the volume is at maximum and I smoothly slide
my hand from lowest to highest note and then highest to lowest note or
if I play notes two or more notes with one no higher than the 7th black
key from the left and the other note no lower than the 10th key from the
right. Actually any combinations of this tone will resemble what I would
hear on my 2 GHz receiver.

#96 ï¿½bass/pianoï¿½ when the volume is at maximum and I press the lowest key.

All the sounds I hear on the receiver are those that result from the
radio waves emitted by the magnetic fields of objects in the distant
cosmos -- such as magnetars. At times, when the magnetic objects cause
magnetic vibrations at an RF-rate, they cause radio waves to be
generated. If the rates include 2-billions-vibrations-per-second, then
my receiver will demodulate the 2 GHz parts and I can hear the signals
-- provided that the demodulations result in frequencies anywhere from
20 to 20,000 Hz [the human hearing range].

Grumph! (but the 150' tower impresses me! <grin!>)

>My best advice is to put up a dipole for 30 meters, even if you have
>to bend the ends to make it fit your space...

Well, a halfwave 30m dipole comes out to... 49 feet?

I went back and checked the NIST "Time and Frequency Services" PDF
file. According to this, WWV-10MHz comes off "half-wave vertical
antennas that radiate omnidirectional patterns."

Maybe I can wind my two 24.5' wires into vertical-axis helices?
<grin!>

> ... A horizontal dipole
>being balanced picks up less vertically polarized noise than
>vertical antennas... Getting the wire outdoors will help also...
>You are likely picking up lots of humm and buzz inside the building
>from various electrical and electronic devices...

Not sure what you could be referring to... other than the three
computers, 25" monitor, printer, Atmel AVR development board (8MHz

clock), flourescent desk lamp, and overhead I-look-like-an-
incandescent flourescent helix... all within 3 feet of the antenna
and clock. <grin!>

>The other issue is whether your clock is actually able to synch with
>the WWV signal... You may have a defect in the clock... It would
>seem that 4 or 5 bars should have done the trick...

If it _never_ sync-ed I'd be strongly leaning toward your way of
thinking. In the past, with a "dangling wire" antenna, it has
occasionally taken months to get in sync; with my two loops I've
managed to get it in sync three times (IIRC) in the past two weeks.
(If I were still rational on the subject, I'd just admit that I
have seen improvement -- all the way from "completely
undependable" to "approaching acceptable" -- even if it's not quite
as much as I'd hoped for.)

Thanks again.

>Presumably the LED meter indicates recieved power, not signal to
>noise ratio.

Exactly. It's an LED bargraph driven by pin 9 on the TDA1072A chip;
according to the data sheet that's the "Field strength indicator
output", a log-scale output driven by the internal AGC amplifier.

I got a clearer WWV signal the other day and was able to re-tune my
antenna. It turns out that the "loud signal" I was tuning to wasn't
WWV, just some random RF I was overloading my poor clock with. The
bargraph now sits down at 1-2 LEDs most of the time, although I did
see a "bursty" period this morning where it went up to 3-5 LEDs.

The WWV audio was coming and going on about a five-second interval:
louder (almost clear), then softer (almost to disappearing), then
louder again. "Wow", so to speak. <grin!>

Ah, well. Maybe in my Copious Free Time I'll replace the MAC-II's
87C52 with something I understand, like an AVR, and program it _my_
way. (Oh. Then _I_ get the support calls. ... Ack!)

Okay, Rick, you've convinced me. The heck with Oklahoma! (Sorry,
MH.) I'm running my antenna line to New Jersey! <grin!>

If I've sounded reluctant to put an antenna up in the attic, it's
partly that I'm reluctant to drill holes through walls and ceilings
to run the antenna cable without at least _some_ assurance that the
results would be worth it... and partly that I'm just reluctant to
drill holes, spackle, and paint. I suppose I could run the line
through the attic hatch door rim and down the hallway ceiling...

>PS may I throw in a little commercial for my pet peeve? As you read

Well, yes. The original post was a bit long and should have been
trimmed as appropriate, but a couple of lines (see above) would have
made things a little clearer to some poor soul who ran across the
post in isolation.

In any case, thanks for the feedback. Let's see... 300 miles of
10-Base2 cable...

Um... 10m? I was hoping for 10MHz/30m. Or have I missed
something? (Wouldn't surprise me -- my 1st Class ticket expired
several decades back.)

Okay... ARRL Antennas, Chapter 8: Multielement Arrays. We've got
an (approximately, given skip) vertically-polarized 10MHz signal, so
the E-field is moving up and down and the wavefront is a circular
ripple (nearly a straight line by the time it gets to Richmond)
travelling roughly west-to-east, that is, it's hitting my house
end-on.

>Dimensions shouldn't be that critical for receive only, and space
>the elements at about 2.5 metres. Basically one element at about 47
>feet, one at about 49.3 feet, and one at about 45 feet. Split the
>47 ft one into two, feed it directly with 50 ohm coax, one side to
>the shield, one to the centre conductor, and you have a three
>element wire beam pointed, hopefully, west. (Put the longest
>element on the east side, the shortest on the west.)

Um... if I label them as A/47ft, B/49ft, and C/45ft, the picture I
come up with looks like this from overhead:

```
| | |
| | |
<--- To Fort Collins | + |
| + |
| | |
| | |
(scale)
```

```
|.........................................C.A.B
```

I definitely think I'm missing something, but then, I haven't really
made it that far into the Antenna Handbook.

Anyway, thanks for the suggestion.

With all that hardware, wouldn't NTP (internet time) be a better option? Or if you are not too deep into steel and concrete a GPS receiver?

Gene, you are just showing your ignorance of physics.
What is it about the word "equilibrium" that you can't understand?
How on earth can you say you are educated in physics?
How is it that you do not have an understanding of Gauss?
Or are you trying to be funny with the word "Artisian-Gaussian"
like the rest of your fellow school boys?
What manner of man are you trying to project of yourself to other
readers of this group, a comedian or an ignoramous or somebody with
senior moments in
continuos series? You never seem to have anything to say that is
informative so why the need to draw attention to yourself.

What is missing in your life such that you have to mimic a fool that
want's to be funny in the absence of a education of any sort?
Back to the Vincent antenna, he has designed an antenna that is
shorter
than that known before. You didn't come up with it he did. He has a
patent
based on his claims and not for the introductory writing.An engineer
in automobiles
has shown interest in it where you have never gained outside interests
in any thing
you have done in your life time. The input impedance is an advantage
over similar antennas
and at the same time not requiring a ground plain without being a
problem to the transmitter.
He is also radiating well in comparison to the height of antenna and
the
radiating system has the appearance of being efficient. Vincent has
come up with something new
and because of the 'not invented in my backyard' you want to diminish
his achievements.
But you can't diminish his achievments without providing an
engineering analysis
and for that you do not have the necessary education.
Maybe it is better that you continue to mimic a fool that wants to be
funny but
better to become a succes at that at home before showing off your
skills in public
even tho you are getting laughter, not with you but at you.

By all means, check out Paul Kiciak's web pages at http://n2pk.com/.
That relatively inexpensive project yields a serious network
analyzer. There are lurkers here (and probably more that read
rec.radio.amateur.homebrew) that have built it and can give you first-
hand info about it. If I didn't already have an HP analyzer and
access to others, I'd have built one long ago.

Cheers,
Tom

Hi Scotty,

When reconfiguring my sloping single-wire 80m dipole into a 4-wire cage inverted vee, I made use of the corner posts of my chainlink fence. I found the ID to be about 2.05" and slipped two 10' sections of 1-1/2" iron pipe (about 1.91" OD) into & attached-to each of the fence posts. One corner post is short (about 3' above ground) and the other is taller (about 6' above ground). I use conduit couplings to join the sections, since they engage more of the threads on the pipe as compared to water pipe couplings. It hasn't been up very long but, so far, so good. If you want to know how well it holds up, ask me after the Winter storms!

What? You don't see cutting the capacitance between winding turns as causing some measurable effect which in turn affects a property of the antenna proper?

Thicker conductor(s) usually means a measurable gain in bandwith, with a parasitic element in such close proximity to the major element, a gain in bandwidth is not that difficult to propose and attempt to prove/disprove.

Personally, my major complaint is in the "lack of control" over antenna performance/operating characteristics.

For instance, with the feed-line allowed to radiate, movement/placement of the coax tends to affect SWR, radiation pattern(s), etc.--sometimes dramatically. This is very undesirable, at least to me, in a mobile/field-day/camping/etc. antenna ...

http://groups.google.com/group/sci.physics/msg/251e17b76b147438 :

> Why just an AM signal? How about a 2 GHz FM signal?

Because AM is more receptive of weak and distant RF signals produced by magnetic objects far out in the cosmos. FM is immune to such interference which is why FM is commonly used for wireless analog audio devices -- such as audio component of analog television signals as well as analog cell phones. If these devices used AM, they would be full of the terrifying-yet-enjoyable sounds I described. These sounds are distracting because of the emotional response to them. It hinders the users from talking on the cell phone or enjoying their favorite show. The listeners get terrified of the sounds. The cosmic magnetic audio disturbances on AM radio cause listeners to enter a dissociative psychological state. While this maybe pleasurable, it can also be extremely frightening.

FM was invented to prevent listeners from experiencing such nightmarish trances. FM audio does hiss when the station is too weak or signal is lost but there are no mind-altering sounds -- like those on the AM radio -- that would disrupt the emotional stability of the listeners. This is because most cosmically-occurring magnetically-induced RF signals are amplitude-modulated in nature. Hence they are received on the AM frequency which the receiver resonates at.

As I've said before, UHFs are the ï¿½sweet-spotï¿½ of radio waves. They are high-frequency-enough not to be attenuated by objects that block longer-wave radio signals yet low-frequency-enough not to be attenuated by objects that block SHFs [3 GHz to 30 GHz range], EHFs [30 GHz to 300 GHz range], THz-radiation, or IR. This makes UHF frequencies more vulnerable -- than other bands -- to cosmically-occurring magnetically-induced RF signals.

I chose 2 GHz because:

A. UHF is between 300 MHz to 3 GHz
B. 3 GHz minus 300 MHz = 2700000000 or 2.7 GHz
C. 2700000000/2 = 1350000000 or 1.35 GHz
D. 1.35 GHz + 300 MHz = 1650000000 or 1.65 GHz
E. Round 1.65 GHz to 1.7 GHz
F. Round 1.7 GHz to 2 GHz

That's why I chose 2 GHz.

http://en.wikipedia.org/wiki/Uhf

"Ultra high frequency (UHF) designates a range (band) of electromagnetic
waves whose frequency is between 300 MHz and 3 GHz, which is 300 MHz to
3,000 MHz."

Clearly this includes 2 GHz.

> you getting this crap from a comic book?

No. It's much more complicated than that.

My birthdate is 10-22-83. On the end of December of '89 -- around a week
before Christmas -- I experienced a blow to my head that cause me to
feel like I was in a different universe. I was playing basketball in my
school, I ran after the ball trying to catch it, but instead hit my head
on a metal pole [used to hold a tetherball].

My symptoms because much worse after January of '90. The symptoms ended
in the end of May of '91. Ironically, the headache was not severe and
only lasted about a day after the injury.

The symptoms were mostly psychological but very frightening. Strangely, they were scary and enjoyable at the same time.

Here were my symptoms:

1. Paroxysmal dissociative states

2. Flashbacks of my house in Stamford, Connecticut [which my parents and I moved out in July of '86]

3. Abnormal dreams consisting of Stamford, the sun suddenly losing its light [causing the sky to go dark], as well as sounds emitted by electronic devices [such the interference on the AM radio and heterodyne tones], and computer error messages.

4. Obsession with outer space, magnetism, as well as the strange sounds emitted by electronic equipment. I used to often play my Nintendo when it was connected to channel 3. However, I was change the TV channel to 4. I could see the video of the game but it was fuzzy and covered in grains. The music of the game was absent, and instead was filled with frightening-yet-enjoyable tones [sounding like a buzzer, lawn mower, or electric shaver] along with a faint audio of what was being discussed on the channel 4 news. I would get so scared, yet I would enjoy it. I would get scared when I saw computer error messages -- especially if I knew they were resulting from some remote network issues -- yet I would enjoy it too. My dad's PC used Windows 3.0 at the time and had a dial-up internet connection. There were often errors on this PC when I used it. These errors related to some distant malfunction. Again, this was pleasurable and scary for me at the same time.

5. Whenever I would change or look at the settings on the TV, I would often see the inside my Stamford home. Particularly the "CATV" sign caused me to see into the hallway and one of the bedrooms in my Stamford home.

6. At night, the sounds of the dogs barking would really scare me -- for no reason. I'd have to plug my ears and close all the windows [to soften the barks] in order to be in peace. I would also get similarly scared -- again, only at night -- when the lights of passing cars reflected off the walls of my rooms, so I would always close the curtains to block the car lights.

7. On the school bus, I would feel disconnected and terrified when the CB radio emitted sounds consisting of radio-frequency interferences.

8. I got a score of -- out of what, I don't remember -- on my spelling test. When I looked at the '5', pictures of my Stamford home began to flicker in my eyes.

9. Paroxysmal Out-of-body experiences

10. Paroxysmal Visual and auditory hallucinations

11. Paroxysmal periods where my sense of time would be shortened dramatically -- 5 hour felt like 5 minutes.

12. Panic attacks

13. Trance-like states

From Jan of '90 to May of '91, my world was filled with these terrifying-yet-enjoyable symptoms.

On 9-9-90, I had probably one of the most strange and scary symptoms. I was fully awake yet I got the feeling that I was going to start dreaming. It was the feeling I usually get if I wake up in the middle of the night and then experience sleep paralysis. There is a strange feeling I will usually get [a warning] before sleep paralysis sets in and I start to dream -- usually in the form of nightmares. I can't remember what happened on 9-9-90 after the 'warning'. I do know that there was no paralysis.

I didn't tell my family about this head injury until recently. I didn't think it was that important. The day of the injury, I had a mild-headache and experienced mild versions of the about 13 symptoms. However, the pain was gone, the next day. Hence, being the naive kid I was, thought that it wasn't of concern. The 13 symptoms also temporarily subsided after the next day, however, it re-surfaced tremendously as New Years approached. At Jan of '90 an onwards it became emotionally-unbearable for me. Finally ending in May of '91.

Whoa! Well this explains a LOT! The hard part of this kind of thing
is to be able to carefully separate extrasensory reality from pure
imagination. Tesla, you may recall suffered from similar symptoms his
whole life. Ended in 91? Judging from you posts it's not over yet.

yep, I had the same thing once, try wrapping yourself up with duck tape,
leaving an inch or two for breath-ability, and stay that way for a few days.

I have never felt better when they took the tape off. Man, what a treatment.

Sounds like OP is really interested in bringing his father's WWV clock
to life.

But if correct time is the objective, ntp is easy. Over the internet
it is supposed to be accurate to tens of milliseconds. On our network,
1 - 5 ms is typical, but I suppose it is quite well behaved.

A GPS intended for timing gives better than 100 ms accuracy off the
cable. It can discipline ntp on a computer to typically 1 - 10 us
accuracy.

It looks like the Garmin GPS 18lvc us the timing GPS of choice for
hobbyists. You need a pulse per second (PPS) signal. There are other
GPS dongles which don't have PPS on the plug, but you can find the signal on
the circuit board.

More info at TAPR: "http://www.tapr.org". See also the timekeepers
mailing list archive:
"http://fortytwo.ch/mailman/pipermail/timekeepers/".

John Ackerman N8UR is an authority on timing and ham radio.

But again - this is probably not what you're really after :-)

I looked around and found http://www.mfjenterprises.com/
Their MFJ-1020C looks interesting.

For now, though, I think I want to concentrate on getting as much as
I can from "bare wire".

>Placing it outside would help. Placing it outside and away from noise

>mini-coax. This would make it easier to hide and you may be able to use it.

The old GC-1000 had a built-in whip; the GCW-1001 doesn't even have
that... just a threaded 50ohm coax connector.

>If you are handy with building things, there are lots of designs for similar

I like that -- there's a window/storm window about 4' away facing
east.

As to your other post...

Both of these would be excellent ways of keeping an accurate time source at hand, and it would be perfectly reasonable to assume that that was what I was trying to accomplish. I apologize for the lack of clarity; let me back up a bit.

When I started out, I simply wanted to learn about how antennas worked, how an EM wave made it from point A to point B in a way that would let me... how do I say it? "Fit all the pieces together"? And, as part of that, I was trying to see how well I could take basic principles and make-with-my-hands something that demonstrated that (a) I had understood correctly and that (b) I could actually build something that worked.

I'd had the MAC-II around for more than three years, sitting in the background and mildly annoying me because every power hiccup reset the display to its startup "not SEt" text and it could be months before it was running again. Mildly annoying, but I didn't have a serious need to know exactly what time it was.

It occurred to me (eventually <grin!>) that building An Antenna that made the MAC-II a more dependable TOD source would be a Really Good Test Of My Antenna Building Skills... sort of like learning to swim by jumping off a dock. As silly as that may sound, when you're venturing into unfamiliar territory (and as a consultant, I do a lot of that) there's always a new kind of swimming to learn, and there always seems to be a dock you eventually wind up jumping off if you're going to learn very much.

So if it looks like my "stroke" is extremely poor at this point, well, that's likely; on the other hand, I'm not exactly drowning, either. I'm waving my hands in all directions, learning what seems to make me move and what doesn't, and listening to helpful comments from the Peanut Gallery on the dock. Youse guys. <grin!>

Throwing money at the prob... er, "adopting a pre-packaged solution" <grin!> gets me the Time Of Day -- precise, reliable, hopefully accurate -- but it doesn't help me learn how to swim... er, build antennas. And, besides, my budget is a bit tight at this point, which means no new test equipment... I don't suppose anyone knows how to generate an accurate 10MHz alignment signal by rubbing a 1.5MHz Function Generator and a Tek465 'scope together? <grin!>

Okay... I'm sure that's more than most (all?) of you wanted to know. Please feel free to recycle this post in an environmentally

acceptable manner. <grin!>

It's hard to tell exactly how much the clock is off by.

Every time the power hiccups, or I have to move the MAC-II, or power
down the outlet the display switches to something like this (best
viewed with a fixed-width font):

```
_ _
_ _ /_ /_ /_ /_
/ / /_/ /_ _/ /_ /_
```

and it stays that way for weeks. Or months.

>As Reggie would have chimed in at this point "If you can't measure it

Hm... I don't _think_ so. At least, I havent heard of any plans for
a High-Def upgrade to Usenet lately, but with Congress currently in
session I suppose anything is possible.

As for testing the clock's accuracy, you're right about needing a second source ("Qui custodiet ipsos custodes?" or something like that? <grin>). On the other hand, as long as the digits are flashing by, I'm happy to "just trust them".

If I read the MAC-II manual correctly, each time it "connects to WWV" (gets a recognizable signal) it calculates and saves an adjustment value. The front panel has two LEDs labelled "TRIM UP" and "TRIM DN" to indicate how well it's doing.

> ... You would be hard pressed to confirm this

>been silent to this issue).

True. And, while I'm sure the _WWV_ announcer hasn't been silent, _I_ haven't heard anything comprehendable from him/her/it out of my MAC-II's speaker at any point in the past few weeks.

>These worst case errors all presume that the internal circuitry cannot

Based on the feedback from other posters, it's likely a consequence of 10MHz propagation. A VLF RF signal like 60KHz reportedly does a much better job of getting a readable signal to a wide area.

>The clock synchronizing circuits don't have to listen to the bandwidth
>of noise you hear, the speaker is for your convenience, not the
>clock's. I am sure that it works fine with only 1 LED lit - this is
>not a case of "can you hear me now?"

No, but (assuming you're subbing for WWV <grin!>) it would be nice to know I was going to get a readable message from "you" more than once every couple of months. (Why do I hear the echo of my parents' frustration during my colege days? <grin!>)

Thanks for the feedback. I admit I hadn't thought that much about
the accuracy of the MAC-II; I'm afraid I've been too caught up in
simply trying to get digits instead of "error text" on the display.

> But again - this is probably not what you're really after :-)

A totaly different approach occured to me when I found that there were no time signals readable here. WWV, CHU (if it is still around) and their European equivalents never seem to be readable here.

The 60 kHz WWV coverage map puts me almost a 1000 miles beyond the edge of their "weak but occasionaly useable" (my words) propigation. Someone on another list claims his clock syncs about 30 miles north and at sea level, but he never answered a question of too what and how often. :-(

What I thought of doing was sort of an radio to NTP interface. Access the time information via NTP and then modulate a signal with it. 10 mHz would be more difficult, you might be able to get 60kHz with a sound card, or something like it. Obviously, you would not need or want anything very strong and you may be able to couple it directly to the antenna socket.

I know it would be cheating, but it seems like a fun hardware/software project. You probably could get a magazine article published about it, and maybe even sell enough boards to to offset the cost of making them.

Geoff.

> made it that far into the Antenna Handbook.

While you're looking at the ARRL Antenna Book, look over the chapter on propagation. You'll find that when receiving a signal by ionospheric skip (as you are), the polarization will be randomly oriented. So there's no point in choosing your antenna orientation on the basis of some supposed wave polarization. Its orientation will, however, have a striking impact on its pattern, so you should choose the orientation to get the most favorable pattern.

The fading in and out of the WWV signal you described in an earlier posting is very likely due largely or at least partially to polarization shift -- the signal fades when the polarization rotates to be crosswise to your antenna, and gets loud when the polarization lines up with your antenna's. I've seen tens of dB difference switching between a vertically and horizontally polarized antenna, with the change going the other way after a minute or so when the polarization rotates. If your receiver needs a constantly strong signal, you're going to have a hard time getting it what it needs.

I haven't followed the thread closely, so please pardon me if I've missed something. Your initial description of the problem sounded like receiver overload. A sharp preselector would help a lot, although it sounded like you were using a tuned loop which, if carefully balanced, should provide that function. If a preselector isn't enough, the next step is to add an attenuator -- I have to use one between my TV and its antenna, in fact. You should consider the possibility that the 10 MHz WWV signal itself is overloading the receiver, in which case an attenuator is necessary, and the last thing you'd want to do is use a better antenna. A directional antenna can be used to reduce the strength of interfering signals if they're coming from directions different than WWV. But making an antenna which has good rejection in the right directions can be something of a project.

During field day we had a similar problem. meaal mast, supporting a long antenna fed with open wire line. Initial thought was that we would make brackets out of PVC pipe and tie wrap them to the mast. This woud require some fairly large and expensive PVC T connectors . Instead we purchased a few lengths of 3/4" Pvc pipe and made a second mast running paralell with the main mast to support the feedline.

A whip antenna should be able to sort out WWV for at least one of 1400
synchronizing events in a day. This may be a problem of too much
antenna at one time - and a nearby lightning event at that same time.
Your front end got fried out.

Did you think I was being sarcastic, Cecil?

The medium brings much unwanted signal to my antenna in my car. Whether it is Art's particles, phlogiston, ether, intelligently designed thingies, or whatever, it isn't wanted.

The medium brings much unwanted signal to my antenna in my car.
Whether
it is Art's particles, phlogiston, ether, intelligently designed
thingies, or whatever, it isn't wanted.

And your point is?

Why not take the GPS disciplined oscillator (e.g. a Z8301) and use that
to synthesize a fake WWV signal (which you could program up in the AVR),
and radiate that to your MACII. You can easily divide down the 10 MHz
from the oscillator to generate all the needed modulations for WWV (the
tones, ticks, and 100 Hz timecode). Synthesizing the voice
announcements might be a bit more challenging <grin> "At the tone,

Coordinated Universal Time is...." You could even have a switch to
change back and forth between WWV and WWVH.

One needs three clocks.. if you have only two, you only know that they differ. If you have three, you can detect the failed clock, because the other two read the same time.

Of course, if the different clocks have different accuracies or reliabilities, that's another story.

For a more detailed treatment of such things, you might want to check out the "Byzantine General" problem.

Although in my house (southern California), the 60 kHz signal seems to fade in and out on a daily basis.

I see billions of dollars will be spent on investigating 'dark matter'
and 'dark energy' and that scam takes some doing but it pales in
comparison to the original imaginative junk of Newton/Flamsteed.

You have all the self-assurances of somebody who truly believes in
what would normally be harmless nonsense but unfortunately the same
people who believe in the junk are commenting on climate as 'experts'.

2214. Low Noise Receiving antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-11 17:38:47 UTC

Message-ID: <wZqdnfQWw5AZwpPanZ2dnUVZ_sCtnZ2d@hawaiiantel.net>
Source record: 35546

I live in a neighborhood that as the years have gone on
has added a number of new homes. This has increased the
electrical "noise" for me where S1 or S2 on 80 meters 6-8 yrs ago
is now S7 to S9. At this point in time I don't have the room for a K9AY
setup. I can only "dream" of a beverage.

I have a Timewave ANC-4 which works very well on 40 meters as I can null out
ALL the "noise".

Not so on 80 meters as it only knocks it down 2 S Units.
At best I have an S-6 noise level.

This leads me to believe that I need a separate sensing antenna for 80
meters. Anyone have any ideas for this problem? Is this thinking correct?

I have been looking at low noise receiving loops and other low noise
antennas. Wellbrook at http://www.wellbrook.uk.com/ seems to have some
interresting possibilities, but some of the reviews I have read have made me
hesistant to purchase any of their products.

What I need is some serious input from anyone who has any experience and
knowledge in dealing with low band noise issues.
As I am now space limited due to all the new neighbors any solution would
need to take this into consideration.

TIA

Talking clock programs have been around for a long time. All you need
is samples for 0 through 24, 30, 40, and 50 and a few words. You could
even play games with it, I'm sure the clock does not care, for
example "At the beep, the fake univeristy time is" and so on.

You really don't need to do much at all, since if I remember correctly,
it's an AM modulated signal, with no modulation also being no carrier.
Am modulation and on/off switching of a high power radio signal is
fairly complex, but at the microwatt level it should be easy.

It's fairly slow so even a reed relay connected to a GPIO line
would do. I'm sure there are all sorts of digitaly controlled
analog switch chips that will quickly and cleanly switch 10mHz.

As an aside, if I remember correctly, the 60kHz version is just
pulse code modulation of a carrier at a very slow baud rate,
so it would be really easy.

Geoff.

I would start with a T2FD. It's simple to build and cheap. The only expensive
part is the loading resistor which for receiving only can be a 1/4 watt.

A balun would help, for receiving you can use a TV balun.

Each one has its benefits and its costs. How much you want to spend on an
antenna is a personal decisison and unfortunately, you can't tell if it
really does anything for you until you have bought it.

An other possibility is to use an active antenna and mount it high up.

Geoff.

I am confused.....are you suggesting I use a T2FD for a noise sensing antenna to be used with my ANC-4?

Or should I take down my vertical transmitting antenna and replace it with a T2FD?

The vertical I use works extremely well for transmitting, its not going away. What I need is a solution to the noise. Which would be a low noise receive only antenna of some type.

I do believe that any antenna's performance is entirely dependent on the environment its in.

Hi Gene, From the data posted by Vincent I dont think he is trying to be a fraud. Maybe he is just unaware that the data he is discovering about short antennas is about 70 or 80 years old. That would be giving him the benifit of the doubt.

What kind of sense antenna are you currently using? I use an active
whip as a sense antenna (specifically, an H-800 "Skymatch" antenna)
and it enables me to squash *any* noise on 80 meters using my ANC-4.

John,

The effects you mention may have some impact on bandwidth, but they don't double it. And the capacitance probably increases, not decreases. Placing an extra conductor between two capacitor plates increases the capacitance. At the same time placing a grounded shield between two capacitor plates reduces or eliminates the coupling between the original plates. It is not clear to me which effect would dominate in this case. In either case it is unlikely to be very important.

Lots of people understand how to make an antenna broadband; simply add resistance. This is not always "bad". It is merely a choice.

Just for grins I did a little EZNEC experiment. I started with a base loaded monopole that used a generated helix as the loading coil. I adjusted and resonated the system to SWR = 1 and took a look at the

bandwidth. I arbitrarily took SWR = 2 as the bandwidth limits. I then added a parasitic winding between the turns of the helix. This winding was not connected to anything. I reran the simulations.

What I found was interesting, but not surprising.

When the wires were treated as lossless, there was virtually no difference in bandwidth or any other parameter. The parasitic winding had essentially no impact.

When I changed the wires to copper, the bandwidth increased in both cases. However, in the case with the parasitic winding the new bandwidth was 2.5 times as large as the case without the extra winding. The resonant input impedance was also about 2.5 times larger.

There is only one plausible explanation for this observation. The parasitic winding adds loss to the antenna system. I won't claim this is "bad". Depends on the characteristics desired.

The bottom line is that there is no wondrous invention here. Either Vincent knew about this effect and chose to ignore it, or he did not understand what was happening. The capacitance explanation is just baloney.

73,
Gene
W4SZ

Neither. I was suggesting (and obviously not very well) that you use it as
a receiving antenna. It's very low noise. It makes a good transmitting
antenna too, but you need to have a big enough balun and termination
resistor to handle the power.

Geoff.

Gee, all this trouble you're having getting a good signal from WWV on 10MHz makes me wonder, "why??" I mean, why bother? It must be the challenge! I'm a bit closer to Ft. Collins, but I wouldn't expect things to be all that much different, and in any event, the same antenna I've used for them has worked fine for signals from W1AW, for frequency measuring tests. That antenna is just a short piece of wire, maybe five feet long, connected to a signal analyzer's input port. The signal analyzer's input doesn't even have a particularly good noise figure. But with it, I get a good enough signal from WWV to easily track the nocturnal/diurnal frequency shifts that happen as the path length changes. (The analyzer may not have a great RF front end, but it has a very stable frequency reference...) Similarly, I have a portable short wave radio that has an awful front end, and with just a 3 foot whip antenna, it gets WWV 10MHz fine most of the time. Obviously, there are times of the day when propagation just doesn't do it, but over the period of one day, and not during a geomagnetic storm, the signal is usually available.

All this makes me wonder if the receiver in your clock is OK. I'd start by looking at that; or at very least, see if a known-working radio receiver has as much trouble with the signal as the clock seems to. Given that the clock has a single frequency receiver, even a pretty simple receiver design should give decent performance.

It's also possible that you have some signal source on nominally 10MHz nearby, and you hear than instead of WWV. There are soooo many microprocessors around the average home these days that it's entirely possible that the source of the trouble is very nearby--but could also be in a neighbor's house (or car -- or garage -- or ??).

If you want an accurate clock and get tired of fooling with WWV-10MHz, and don't want to use WWVB-60kHz, you might consider using a GPS. As long as you can manage an antenna with a reasonably clear view of the sky, you should be able to have a clock reliably set to within less than a second accuracy practically all the time. Or, if you'd like to be independent of external references, modify your MAC with an oven oscillator. Oven stabilized crystal oscillators left on for a long time will almost always settle out to very low drift rates---one part in 10^8 over a year shouldn't be difficult, in my experience, and GPS signals can be used to calibrate it occasionally. One part in 10^8 is about 1/3 of a second per year.

Cheers,
Tom

IMO, we are already into the next ice age, the global
warming temperature having peaked some 8000 years ago.

I use a small dipole like antenna where one half is at 45 degrees the feed
point is a few inches above ground and the other side runs paralle to
ground about 1-2 inches above ground. I think the whole sense antenna is
about 6 ft long and runs in a straight line.

I will look up the H-800 on the web.

Did you try various antennas and configurations before you settled on the
H-800? What made you decide to go with the H-800?

I tried different "antennas" and configurations, for this location this has
worked out the best that I have found. I do realize there could be a

zazillion different antennas and configurations.

This could be a very interesting experiment. Try the
T2FD but in steps.

1. Ordinary horizontal single-wire dipole

2. Ordinary horizontal folded dipole

3. T2FD

Reporting the noise on those three configurations
vs the vertical would be of wide interest.

Your suggestion is a good one. I found some construction plans, all I need
is the stuff to build it with.
I think it would make an excellent sense antenna, but won't know until I try
it to be sure.
Any idea if it shows any directivity?

well, I already use a shortened dipole which has one leg at 45 degrees (the end is somewhere between 2.5 to 4 ft high, I have not measured it) to the feed point that is about 2 to 3 inches off the ground and the other leg is about 1 to 2 inches off the ground.

I don't use it directly into the receiver, I suppose I could, but I use the Timewave ANC-4 for reducing noise and its my noise sense antenna.

Obviously this one as I mentioned works extremely well on 40 meters, I can null out all noise, the S meter lays flat on S1, but the 80 meter performance is poor.

I would like to try the other antennas you mentioned as sense antennas, the problem is do I go full size on the folded dipole? I think I need to go full size with the T2FD in order to get it to work correctly.

How high above ground do I need to get it?

I tried lots and lots of different sense antennas and got varying results. The H-800 gives me the best results from among all the sense antennas I've tried, though of course this could be a function of the particular kinds of noise present at my QTH.

I will say this. Because I live in an urban area it's been my aim to defeat RFI in every way possible. I use one of the Wellbrook loops and that helps, but nothing has been as big a help as the ANC-4 WHEN MATCHED with the right sense antenna.

Part of me suspects that the ideal setup, at least for me, would involve having a couple of different active whips to switch back and forth between. I think the H-800 does well on 80 meters because it's quite sensitive there. However, it's quite a bit less sensitive on, say, 20 meters and I'll bet I'd get better results using a different active whip, or perhaps a wire, on higher frequencies.

I have never considered an active antenna for the sense antenna.
Maybe that would work here.
I wonder if anyone else is doing the same thing or if you have "found"
something really unique.

I know at least one other person who does it. He uses one of the McKay-
Dymek whips. I tried the H-800 simply because I already had it laying
around. I couldn't quite see buying an H-800 just for use as a sense
antenna, as they're fairly expensive, but I've seen them go on ebay
for not too much.

Active whips can be real noise magnets. A huge disadvantage if you're
using one as your receive antenna, but a big plus if noise is what you
want it to hear!

But what you are saying is when you use the active antenna with the ANC-4
it works very well for cancelling out the noise.

You can easily verify this by noting the change in gain as the extra winding is added and deleted. You should also see a corresponding change in feedpoint resistance, assuming that the extra winding doesn't change the current distribution. A couple of additional interesting experiments would be:

1. Increase the loss of the coil in a model without the extra winding until the gain is the same as the model with copper loss and no extra winding. Then see how the bandwidth compares to the original model with extra winding.

2. Instead of increasing the loss of the coil, add a resistor to the base of the copper loss non-extra winding antenna and adjust it so the gain is the same as for the model with copper loss and extra winding. How does the bandwidth compare to the original model with the extra winding?

I'm afraid that's probably true. With antennas, you can choose any two of efficient, and broadband, and electrically small. This antenna claims all three, so I'm very skeptical.

Hi, Tony.
Several years ago I decided to put my ham radio station back on the air. The tallest trees on my property here in Central Oregon are junipers, about 35 feet tall. I managed to get the ends of a 40 meter dipole up towards the top of the trees. It was fed with coax and a balun. Petty noisy.

Later, I decided to try the old tried and true folded dipole using 300 ohm TV twinlead and an antenna tuner. This time I was able to get a 75 meter antenna up into the junipers. When I connected the antenna/tuner the receiver, there was no noise. I actually went outside and checked for something shorted. Then I checked the antenna for continuity with an ohm meter. All was ok. This was mid-day and there were no stations on 75 m. I tuned other bands and there was plenty of activity and very little noise. Later I began to hear stations from the mid-west on 75 meters.

Bottom line, I think if you can find the room for a folded dipole or other loop type antenna you will be surprised how much your noise level goes down.

Best of luck.

I dont have EZNEC, But I will trust you if you care to model a 1/4wl
monopole and compare it to an 1/8wl monople operating against a
perfect counterpoise. Fine enginneer that Art is he should have no
trouble in calculating field intensity at a receiving antenna 1 mile
away. I have total respect for the integrity of your work as long as
you show your math.

I am using an older set-up than yours: a Yaesu FT-100D with an ATAS-100. The antenna is mounted on the back hood of a C-series Mercedes, close to the back windscreen, at its center. The ground side of the RF connector is connected to the car body.

SWR is almost 1:1 on all bands except on 10 MHz (where I use a very small MFJ tuner). Performance is incredibly good. I am particularly impressed of its behavior on 40-meters.

Right. The whip is just a noise antenna in my setup.

No.

We are talking about a small antenna ~25% of full 1/4 wave length which performs as well or outperforms its full length 1/4 wave version.

We are talking about a 1/2 wave antenna which is only 20-30% the length of its full length 1/2 wave version which performs as well or even out performs its' full 1/2 wave length ...

Show me an EZNEC model of what the Navy tested for Mr. Vincent--indeed, show me where anyone before Mr. Vincent was able to demonstrate a working model capable of the above characteristics?

Gentlemen,
Vincent did produce a shorter antenna than was known before
with a 50 ohm impedance feed which is a huge advantage for designers
that want to hide, encapsulate or what have you for a small antenna
in this wifi age and nobody can take that away from him even tho his
knoweledge of antennas is limited.
If he understood Gaussian law then he could have made the Gaussian
antenna
which requires an element in equilibrium which means a FULL
WAVELENGTH.
I know you dislike the meaning of the term equilibrium b ut here it
is
indispesable.
Even without the knoweledge of Gauss he came very close to Gauss
or the biggest discovery of the century

If one winds a half wave length in a clockwise direction starting
at the top going down and then repeating with another halfwave length
but winding it in a counterclockwise direction(preferably winding
both
wires at the same time) and then joining together the two wires at the
top
he would then have a copy of my Gaussian antenna.
Note that the errant current flow that Vincent has on the feed line
now has
a path to travel where it can radiate and still have a resistive match
at
the feed points. This by the way is bidirectional
Now one can again expand the Gaussian principle by making the antenna
height
less than the wound diameter to make a circular polarity radiating
antenna.
Also note that Gauss's work then leads to a maximum gain when the
antenna
is at right angles to the earth but knowing that a full summation of
all vectors
on the radiator is around 10 to 12 degrees from the radiator axis the
radiator
when tilted will maximise a particular polarity alone.
You can deride Vincents achievement as something useless but the
Gaussian antenna
is here,it is real and the mathematics regarding the extension of the
Gaussian
aproach gives an insight as to how radiation is really created which
has been
the goal of scientists for more than a hundred years.
And the experts on this newsgroup who were told of this first derided
it also.
Make a sample of a single wound antenna and then make a mirror immage
of same
and joining at the top. Then study it to determine if the windings of
an
inductor represents a portionof the resonant length.....
remember that augument, maybe you should revisit it! Yuri you can
provide
your normal account as to how antennas work in a contrary fashion.
And yes Roy you can repeat your phrase of "I don't understand it{"
As for others with computor programs you can alsomodel it for
yourselves
and then curse your computor.
Regards
Art KB9MZ.....XG

Jimmy,
I don't have eznec either but I can still experiment the old fashioned
way.
As for a recieve antenna by next experiment gyrates in that direction.
Having proved that the inductance and capacitance of a radiator are
acting as energy sinks
that explode when the terminal are closed I am now going to place a
gaussian antenna between
two 8 by 4 sheets of aluminium sheeting which I purchased.I want to
act as a capacitor from which
my antenna will draw energy from to provide a larger aparture for my
antenna for receiving.
Question remains as to how the circuit for the large capacitor turns
out and what amount
of energy it will absorb that I can steal from it to aid my Gaussian
antenna.I suppose

I could resonate the capacitor at the same frequency that I want to
receive!!!!!
It can all be a failure but it will be one less to make in the future.
Art

Probably more than you ever wanted to know about short antennas.

Now a bunch of erronious information
He states for short antennas a good ground field is paramount
which is false. It is correct for a fractional wavelength antenna
but not for a short antenna. Then he goes on to relate a top hat with
efficiency
so the question is does the top hat make radiation per unit
length the same terminology as efficiency since the top hat does not
increase height?
Basically, if you have a fractional wavelength antenna then a ground
plane is
paramount to provide a low resistance to ground (power loss)for the
the ANTENNA circuit.
If a low resistance path to ground is not there then the
system is closed by the outside of the feed sheathing to transmitter
ground
which closes the ANTENNA system providing combination radiation as
well as system loss.
I say again, one must have equilibrium for maximum efficiency and that
requires a full wave length
radiator and at the same time holding to the LC ratio for that
length.
These are cardinal rules as shown by Gauss.
Regards
Art KB9MZ

My first radio was a Yaesu FT8800 mobile. It was necesarry to return it for
service twice in the first 3 months of use. This sort of turned me off on
Yaesu. I replaced the 8800 with a Kenwood TMD700. My base is a Kenwood TS2000
which I like very much. I then bought the Kenwood D7A to replace the Yaesu
handheld. All three Kenwoods have built TNC, and have similar menu structures
for ease of programming and work well with one another for APRS and packet. The
Kenwood mobile is easier to read the display. I am interested in "packet" radio
and the newly developing AVRS combining APRS and IRLP. My Kenwoods should be
good in these areas.

Mild rant: The mfrs are into planned obsolescence, especially on 2 mtr HTs. Unless you are an aficionado of Star-D or other exotic stuff, what do you really need besides digital tuning, PL, and a dozen or so memory channels? Of course, my opinion will offend the Ones who must be the "First Kid on the Block" to have the latest fad item.
Anyway, I really like my Yaesu VX-5, which is available used at reasonable price. It's a 5-watt tri-bander (6,2,70cm)which is software programmable. I was really excited when I bought it, but now find that for my use, it is secondary to a good 50-60 watt mobile when traveling away from the local repeaters. An old Yaesu FT-1500M serves for 2 mtrs.

Hello, and sure, there's a little firm out there called Agilent ;-) What you are seeking is a one-port (reflection measurements only) instrument that can measure the complex RF voltage (or current) reflection coefficient. From that VSWR, return loss and complex (resistance and reactance) impedance can be calculated and displayed. An RF vector network analyzer (VNA) will do all this and more. MFJ has managed to package an affordable but stripped down form of a one-port VNA. (Hey you asked about other companies but didn't say what you were willing to pay.)

Years ago the HP (now Agilent) catalog had an "RF Impedance Meter" that IIRC could make complex impedance measurements in the HF band. It provided display of impedance magnitude and angle using two analog meters. Perhaps one in good working order could be had at a hamfest or fleabay. Sincerely, and 73s from N4GGO,

Short term variation of plus and minus 2.5 degrees
but the temperature envelope for the past 8000 years
shows a downtrend. We are not in an ice age yet
but the present ice age *cycle* began 8000 years
ago. It is possible that the greenhouse gases are
actually delaying the onset of that next ice age which
will eventually destroy America's breadbasket. Al Gore
will become one of the most ridiculed men in US history
(for the Nth time).

2256. Digitale Leeromgeving Zend Amateurs (DLZA)-cursus gratis.

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-12 14:11:48 UTC
From: Delta-India-Golf DX groep <DIGTEAM@delta-india-golf.com>
Message-ID: <op.tz28dy0f8wy0yi@gesoft-zolder>
Source record: 35588

DLZA promotekst

Er zijn overal in het land mensen die graag zendamateur willen worden maar een goede cursusleider, cursuslokaal, of een cursus locatie is schaars, er is al sinds langere tijd weinig nieuwe aanwas in het amateurisme dus een reden te meer om hier iets aan te doen.

Er zijn immers meerdere middelen voorhanden om aan dit probleem een einde te maken, en het internet samen met het Voice over IP programma TEAMSPEAK kunnen we de tegenhangers van de digitale communicatie laten zien dat er veel meer mogelijk is. Het initiatief van zendamateurs en TEAMSPEAK is een van die middelen die het mogelijk maakt om de cursisten die verspreid over het gehele land zijn mee te laten doen aan deze nieuwe opzet.

Het was regelmatig zo dat cursisten vooraf afhaakten omdat ze meerdere kilometers moesten afleggen om bij een cursus aanwezig te kunnen zijn, de reistijd die voorheen verloren ging kan nu gebruikt worden om mee te doen aan deze DLZA-cursus. Als je net even 20 minuten beschikbaar hebt om iets aan de cursus te doen dan kan dat nu, gewoon de computer aan en via internet de cursus volgen. Geen E-mailtje sturen voor huiswerk controle, nee gewoon 100% mondelinge ondersteuning op de TeamSpeakserver met een van de docenten.

Weer of geen weer, je kan gewoon lekker thuis met je eigen koffie en koekie de cursus volgen vanuit je eigen luie stoel achter je eigen computertje. Zo heeft elke cursus opzet voor en nadelen maar van deze opzet blijken de voordelen wel erg veel naar voren te komen. Een ander voordeel van deze DLZA-cursus is dat deze cursus geheel gratis is, geen boeken kopen, geen bijkomende brandstof kosten maar als nadeel wel een internetaansluiting.

De docenten zullen je op de voet volgen bij het maken van de lessen, ze kunnen ook zien welke lessen je al wel of nog niet hebt gelezen, ze controleren de antwoorden en ook je eventuele voortgang. Maak je onnodig veel foutjes dan zullen ze op de TeamSpeak server van de Delta-India-Golf DX Groep graag aan je uitleggen wat een betere aanpak is, gaat alles goed dan luister je gewoon lekker mee in de Studeerkamer op de TeamSpeak server, alleen de cursisten en docenten kunnen in die 'room' een praatje maken, alle andere doen dat in een van de vele andere beschikbare kamers.

Ook is het mogelijk om met de docenten gewoon even prive te gaan in een van de beschikbare prive kamers, daar kun je dan ongestoord je probleem uitleggen, of gewoon vrijelijk praten over je antwoord keuzes zodat andere cursisten dit niet mee kunnen horen. Kortom mogelijkheden te over om allemaal in dit promotieverhaaltje samen te pakken.

De cursus is al beproefd en kent al twee groepen geslaagden die je op de amateurbanden al kan horen, sommige hadden echt nul ervaring met electronica of een andere cursus en lopen nu met het zogenaamde fel begeerde papiertje rond.

Het probleem van nieuwe drukkosten is ons onbekend, al moeten we vermelden dat vele cursisten wel de nodige inktpatronen gebruikt hebben om de cursus uit te printen. Wil je mee doen? Dat kan, lees dan de Aanmeldings procedure A t/m Y die op de hieronder vermelde website te vinden is onder DLZA, daar wordt duidelijk uiteengezet wat je moet doen.

http://www.delta-india-golf.com

Gelieve dit artikel op te nemen in jullie club blad, website, email-lijsten, ronde's of door het te schreeuwen van de daken. Help mee dit DLZA-project te ondersteunen daar waar mogelijk met jullie eigen mogelijkheden, al is het maar om meer amateurs op die banden te krijgen.

Met vriendelijke groeten het DLZA-Team.

Finally, someone gets around to asking for my point. Thank you Denny!

My point in the whole thing was that in here we have BPL Threads,
Receiving 2 GHz AM signals in outer space. Strange threads about
alternative physics. While my query regarding a reasonably on-topic
mobile antenna and RFI problem didn't get a reply until I added an off
topic addition to the subject line.

Hey, I know. Just 'cuz I post it doesn't mean anyone has to answer.

Hi Mike,

A plea for mercy if ever there was one (especially when antenna ghouls
are feasting on the corpse of an old announcement of a "new antenna").
I didn't respond the first time because you clouded the topic with the
introduction of the fuel pump "thwipping" which to me sounded like you
were complaining of an admittedly minor issue.

So, to return to the first part of your post: I will bet your rig's
power or ground is sharing the same fuse/line/ground as the ECM and
noise is being conducted into your rig.

Take the power lead for your rig all the way back to the battery post.
DC ground the rig to the chassis/block connection of the battery.

Adding ferrites to the ECM leads may kill or distort impulse signals
the ECM needs to properly run things.

Can anyone recommend a verical antenna that i can mount on the roof
of
my 3 story house that works from 80m upwards and wont upset the
nighbours (too much). I have looked at various Butternuts etc but it
seems like they only work well when ground mounted. Also keen to get
one that is not to noisy as in a relativly built up area. I would not
operate with more than 100W

I have looked at reviews on EHAM but they all seem to be mixed.

Thanks

Andiroo

How can I believe in time-travel when I don't believe
that time even exists? Some changes are reversible
and some are not. If you want to consider a reversed
change to be time travel be my guest, but I don't
buy it.

A 22 foot antenna with four 22 elevated radials driven
by an SC-230 will do a good job on 40m-10m and not bad
on 75m, at least on CW.

Just out of curiosity, have you tried locating the noise source. I had
the same experience you are having more or less.
I had been away from ham radio for a couple of years and when I fired
it all up again HF was really noisy so I ran the radio off of battery
while I shut down power to my house. I found the source of the noise
was the display on my microwave oven.
Short term solution was keeping the microwave unplugged until needed.
Long term solution was replacing the microwave. I did this when i
found a better one at Goodwill for less than $20. Also check for RF on
the coax during transmit. During rx this means the antenna is also
picking up signals from the shield which may be in close proximity to
noise generators.

I used a roof mounted Butternut HF6V for several years with excellent results. Especially when compared to no antenna at all. Plus I never ran more than 100 watts. That is back before I got my amplifier, way before.

The surprise came when I bought and installed a Van Gordan Shorty All Bander and slopped the vee from the base of the tripod on which the Butternut was mounted down into my backyard. The legs were at a 50 degree angle and the peak (apex at the tripod) was pointed toward the southeast. The Shorty All Bander clearly out performed the HF6V (using steel siding as a counterpoise) on 30 meters downward. They performed about the same on 20 meters upward. The Shorty All Bander would have been invisible to everyone had I used a standoff on my third story and kept everything in the backyard, of which I didn't have much at all.

Today, if I couldn't work it out with the Shorty All Bander, I would buy an autotuner for wire antennas and mount a 30' piece of wire or tubing at ground level and place the tuner at the base, in a protective enclosure. I did discover later on that my Butternut did work a bit better on the ground, but the 50 ohm match went to hell, as predicted by others.

All of the antennas I have mentioned worked well enough for me to easily make contacts all over the world with just 100 watts. Any antenna is

better than no antenna. Don't let the antenna snobs get you down.

Anyone ever taken a moment to measure the values of the balun and
termination network in a B&W End-Fed Vee HF Antenna?

http://www.bwantennas.com/ama/veeant.ama.htm

I'm curious if the Balun is 1:1 and if you've measured the value
the resistive value of the balance network at the end of the wire is?

Your replies and thoughts as to how this antenna works?

thanks

Hi Jimmie,

Praise your wife and read the book - then tell her it's great. Arthur
would probably recommend burning it if the index doesn't include
gaussian librium.

Here's a test. Does it have a formula for the radiation resistance of
an elementary dipole or loop? Both?

What would the formula evaluate the Rr of a quarter-quarterwave sized
vertical? For extra credit (applied to this author), what would be
the reactance? You may have to extrapolate that from a chart, but 10
bonus points (applied to this author) if there's an equation.

Maybe it not the wire but the insulation on the wire, A little dielectric heating would surely make it more broadbanded.

Richard, I found a few excerpts on the internet and found it included in the bibliography of several papers.This looks like a pretty good book. I also noticed it carries a hefty price tag at amazon. I think the wife did well. It way be a while before I can dig into it though. My plate is pretty full right now. I have to go to classes to become the system administrator. for a new computer system. for the next couple of months I am going to be concentrating on that.

I saw someone selling the trerminators for this type of antenna at the
last hamfest I attended, I think it was the Wireman but not sure.

Probably a lot of bad things you could say about this antenna but it
will get you on-the-air with a minimum of fuss. Govt uses these a lot
for network communication where operation and setup is to be perfrmed
by someone of minimal training.

I did a good assessment of the noise being heard here.
I found an electric razor charger that was some of the problem and
a computer printer was another I found.
So my home is quite clean unless something else has popped up which I don't
know about and can't locate.

I test with power on and power off. Right now theres very little difference
if any between the two.

I would think its coming from someplace else, but until I can come up with
the exact location I need to decide on a solution thats effective.

Unreal!

Some of them babies are quite a bit too much for a hobby! Wow. Google
never showed allot of these.

With that in mind, I think I will either purchase the MFJ-269 or the VA1
and RF5 Combo pac from autek. The computer based units though cheaper and
more accurate, would not be always convenient to use.

I don't know the book, but there is a two volume set (one orange, one blue) by Rudge, Milne, Olver and Knight. Those are professional level antenna books. I suspect it is the same Rudge.

If yours is similar, I would think it is a steal at $1. Professional level antenna books can be very expensive.

My background is quite close to their target audance - I did an MSc degree in "Microwaves and Optoelectronics", and one of the options I took during that MSc was "Antennas and Radar".

Yet I'm the first to admit, I find the theory in these sort of books very hard at times. (I think having a maths degree might help, which I do not have).

>enclosure.

Me too - with a 100W transceiver but no antenna, I wouldn't spend a single penny on factory-made HF antennas. Instead, I'd invest that money in a remote auto-ATU that can be used with a wide range of future antennas.

Most of the cost and complication of factory-built multiband antennas comes from the need for impedance matching on each band. With an auto-ATU, those worries are over - any convenient length of wire or tubing will work, and costs almost nothing.

You also have a lot more freedom to play with new antennas. The auto-ATU takes care of the matching chores, while you have all the fun... and that's priceless.

Unfortunately, the picture changes at power levels much above 100W, because the inductors, capacitors and relays suitable for a high-power auto-ATU are very expensive in commercial production quantities. However, there are still plenty of large RF parts available as one-off surplus bargains for individual constructors. It would be an interesting project to strip down a smart modern auto-ATU, ignore the on-board RF parts, and use the bare board as the controller for a much larger home-built ATU (using the same L and C values but with much higher RF voltage and current ratings).

Hello All!

I am planning to put up my first tower and beam, the tower 25g braced to the house at 20 feet 45 ft tall and a Yaesu 800ga rotator.

The Problem!

What Beam to put on top?

I have done my home work and currently trying to decide.

3 element Stepper IR (Looks good but, pricy! On the negative, if a wire bus comes lose or breaks your SOL)

Mosley ta-63 (all band but no f/b)

Mosley classic cl 33 + warc (Looks sturdy but, traps, no gain on 17 meters)

Sommer (looks good but a bit of Rube Goldburg + Heavy)

Force 12 (pop ribits and tuners ???????)

Tennadyne (same gain as 2 element yagi big! Swr)

I hope to here what the opinions are.

Thanks All

WA3YMM

all multi-band antennas are a compromise. its up to you to make the
tradeoffs and pick one that fits your budget and provides the band coverage
you want.

oh, there is one other drawback on the steppir... long delivery time. i am
just about to leave to help a friend put up his that just came in last week,
and he ordered it at Dayton in the spring. if you want to have something up
for winter that may be a problem. if you are planning for spring you should
make it.

Hi David, back to your old tricks again eh?
If you go up a halfwave length and then come down a halfwaveleng you
then
have 2 x 1/2 so you don't have a half wave length anymore.
Watch the childrens hour on TV for the answer

>

You have just got to watch childrens hour to get up to speed for your
mathematics, new math that is.

A gaussian antenna can be any shape, size or configuration as long as
it is in a state of equilibrium

>
> and ONE MORE TIME.... define 'equilibrium'. write the equations. just what
> is in 'equilibrium' with what??

No David I am not going to go thru all that again,get yourself a
physics book or Google around

> just what is in 'equilibrium' with what??

Art posted his definition in this thread on Oct 11. But no math
to support it.

\\ If he understood Gaussian law then he could have made the Gaussian
antenna which requires an element in equilibrium which means a
FULLWAVELENGTH. I know you dislike the meaning of the term equilibrium but
here it is indispesable. //

What I get from his comments is that Art believes fractional wavelength
radiators are inefficient because they are not in equilibrium, ie, they are
not a full wave length and therefore don't act like a tank circuit (he
says) -- which he believes is necessary for efficient radiation.

I've sent Art several emails with NEC results and math-based discussion
showing that a 1/4-wave monopole working against a 2-ohm r-f ground plane
radiates about 95% of the power applied by a matched source between it base
feedpoint and r-f ground. This is the configuration used by virtually all
commercial AM broadcast stations, and its very high system radiation
efficiency has been proven thousands of times since the earliest days of
broadcasting. Of course that is at odds with the beliefs Art continues to
post here and elsewhere.

In a response to my emails Art seemed to understand, and even thanked me for
"sticking with it." But I guess he was not convinced, because he started
this thread _after_ our email exchange.

Since my discussions with Art I put together a chart showing the groundwave
field generated at 1 km by several, fractional wavelength monopoles at
applied powers from 1-10 kW (see link below). I used a perfect ground plane
in preparing the chart, but the values would be only slightly less with a
2-ohm r-f ground.

ART: Note that the 1 kW field for the 1/4-wave monopole is exactly the peak
field of a 1/2-wave dipole in free space (about 313 mV/m). Taller
monopoles generate more groundwave field, given the same applied power and
r-f ground, because their radiation patterns have more gain in the
horizontal plane and less gain in other directions -- not because they are
more "efficient." All of the monopoles in this chart radiate all of the
power applied to them (100% efficient).

Also note, Art, that a 1/2-wave monopole and its ground image comprise a
full-wave antenna (eg, having your "equilibrium"), yet the 195-degree and

225-degree monopoles produce higher groundwave fields, even though they are
NOT by your definition "in equilibrium."

When you said if the Gaussian antenna was real it would have been
invented long ago
or something like that and yet they are still giving out patents and
Nobel
prizes out for things that are newly discovered I lost interest in
your musings.
When you added things like an image is real I have to walk away
because you are
just not on my wavelength. I fed the half wave image and also hooked
it
up to a receiver and I heard nothing, let me know when you make a
contact
or maybe I should dig a little bit deeper!

My son mounted a 5BTV on a 25' push-up mast with 4 elevated radials for 40-10 mtrs and 2 radials for 80 mtrs (22 total radials). We later added the 30 meter mod and it's now essentially a 6BTV. This antenna works like gang busters on 30, 40 and 80 meters. We don't use it much on 20, 15 and 10 because we have other antennas for those bands. Your mileage may vary but from my experience if you can get the 5BTV off the ground and put some elevated radials under it it will perform very nicely for you especially if you like low band DX and don't have a lot of room for antennas.

Regards,

Pat - KZ5J

the basic problem is art that you forget we had a long conversation about what a 'gaussian' antenna in your dream was. and you specifically said a single halfwave dipole was a 'gaussian' antenna. you can go back and search if you like, but i doubt that you will since you have now changed your imaginary antenna. please art, go take a long walk... a very long walk, the fresh air may do you good.

I am completely happy with my Hygain TH3Mk4 at 40 feet, which replaced a Mosley TA33Jr (semi useless). The first day I had it up I worked 3 new countries in the Far East on 15 SSB. On at least one occasion I had Europeans on 20 tell me I had the strongest signal from North America at that time. Duce (sp?) Island came back on the third call.

Probably you'll agree that good, new antenna designs need more
than "the appearance of being efficient." Let's expand on this..

The link below leads to a calculation of the system radiation efficiency and r-f bandwidth of a conventional, 30-degree, base-loaded monopole, using the equations found in standard antenna engineering texts. This is the physical height used for the "standard DLM" antennas tested by the Navy for the University of Rhode Island. The coil and r-f ground loss was set to 2 ohms, total, to approximate the conditions in the U-RI test.

This non-DLM configuration of a short monopole has a system radiation efficiency of about 59%, and for 1 kW of applied power generates an inverse distance groundwave field of 241 mV/m at 1 km.

A standard, 1/4-wave vertical monopole with a matching network and r-f ground loss of 2 ohms, total, is about 95% efficient, and for 1 kW of applied power generates an inverse distance groundwave field of about 306 mV/m at 1 km.

So the field of the 30-degree radiator is about 2.07 dB below that of the 90-degree radiator -- and that is due mostly to the much lower radiation resistance of the 30-degree radiator (about 2.9 ohms vs about 36 ohms) against the 2 ohms of other losses in each system.

The March 31, 2005 U-RI test report states that the 3.5 MHz standard DLM had a measured groundwave field at 1 mile that was 2.33 dB less than the Navy's reference monopole (whose electrical height is not stated, but presumably is 90 degrees). So the measured h-plane gain of that DLM was about 0.26 dB _less_ than a conventional, base-loaded, 30-degree monopole -- although that difference could be within the range of measurement and/or modeling error.

Also note, Art, that the DLM needs a good r-f ground, just as do all monopoles, and especially short ones. The Navy went to great effort to provide a very good r-f ground and propagation path for the range where the DLM was tested.

2297. Splitting a Scanner Antenna's Feed ?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-13 20:39:32 UTC
From: Robert11 <rgsros@notme.com>

Hello,

Have a scanner in which I listen from 25 MHz or so up thru the vhf and uhf scanner frequencies of 1.3 GHz.
Presently, one desktop scanner connected full time to one Scantenna in attic.

Will be buying a handheld scanner, which I will be using (when not being used in a mobile mode) in probably one of three other rooms in house.

I would like to connect a new antenna in the attic also, but have coax brought split out to the three rooms
as ports for the handheld to be plugged into.

Only one of the three ports will ever be used at any time.

a. Do I need a "Coupler" between the three branches from the new antenna's feed ?

b. If not, will the two Unused ports need to be terminated, or is just hanging open fine ?

c. Anything else I should probably be asking about this proposed setup ?

Thanks,
Bob

It is *NOT* in physics either - it is in medical physics, which is a
discipline of its own.

Understand your problem. In the Netherlands we live rather dense to
each other. Consequently when you are a ham and try to receive
something you are confronted with a blanket of man-made noise from
various sources. Mainly they are coming from switched power supplies
in some kind. It's almost impossible to adress all neighbours and
de-noise the equipment. In NL the responsible salesman should remove
these kind of QRM, you will imagine that it will cost a lot of effort
convince him that his product is causing the problem. To get around,
you can sample the noise, reverse it and add it to your antenna
signal. The QRM is simply nulled out. The earlier mentioned ANC-4 is
doing that, however I understood it's not capable to to do the job
very well. Same goes for the MFJ-1025.
Have a look at the page of pa0sim
http://www.pa0sim.nl/Phaser%2080%20-%2010%20meters.htm
Don't worry it's in English and it gives you some ideas how you can
tackle the noise/qrm problem.
If have your QRM sensor is correctly placed for picking up the "noise"
and feedback it, it should do the trick. Alternatively, for those who
have not the man made noise problem, you can null-out a short skip
station in favour of that DX station you would like to work.

Frank -
I am up in Maryland, not too far from you.

WWV on 10MHz is only usable for about a third or less of the day for locking an electronic clock. Generally the late afternoons and evenings are great, early afternoons and mornings are a little more variable.

Overnight 5MHz works best. During the mid-day 15MHz or when propogation permits 20MHz rules for WWV. I don't think your Heath has any frequency diversity capability, right? Well, 10MHz is a pretty good choice if you only have a choice of one, it is usually coming in strong in the evenings there. Over wintertime 5MHz gets pretty good at night.

You will, especially in the early morning, occasionally hear WWVH on 10MHz or 5MHz or 15MHz. Sometimes I hear both WWV and WWVH at the same time. You can recognize WWVH by the woman's voice reading the time.

My best antenna for 10MHz WWV is my 40-meter dipole strung between two trees. Mine mostly points broadside to the NE/SW but if you could arrange it, it would be slightly preferable to have it broadside to be sensitive to the W.

A dipole optimized for 10MHz would be even shorter - the formulas put a half wave dipole at 47 feet long.

Tim.

At least a splitter that provides some isolation among the ports is a
good idea. If you just parallel three terminated lines and connect
them to antenna output, you'll have some mismatch loss--6dB worth.
And if you forget to terminate one or both unused lines, they'll put
lots of nulls in the frequency response.

A splitter won't give you a whole lot more signal, since 2/3 of the
power goes to the terminated lines: you have a loss of 4.8dB in the
ideal case.

A couple of other options: get an amplifier with three outputs; it's
possible to have very good isolation if the amplifier is done right.
Or...run the cable "daisy-chain" fashion, with a little jumper in the
first two rooms. Remove the jumper and connect to the antenna feed if
you want access in that room. Don't need to worry about terminations
that way, just jumpers. Cable loss starts to add up, especially on
UHF, but if the runs aren't too long, it probably beats the loss of a

splitter.

Cheers,
Tom

Richard

Seems like I remeber hearing about AM broadcast towers whose ground resistance was less than 1 ohm(built in a marsh). I would think the Navy's installation would be at least this good. Of course this would only further make your point.

Jimmie

I work on a weather radar that used time data from a WWV rx. the rx was a scanning receiver that would automaticaly switch frequencies when a lock was lost. Sometimes it would go for days without syncing. This got to the point where the WWV rx was replaced with a GPS rx. Problem solved.

Ive done exactly waht you are asking about using a splitter and "bullet"
amp from radio shack. TV distribution amps have filters that may not allow
for all the frequencies you want access to. Place the bullet as close to the
antenna as you can get it. You will have to place the power supply before
the splitter or make sure you have a spliter that will pass power through
it.

I'd love to hear from someone who's tried this phasing unit. If it's really light years ahead of the Timewave and MFJ units, I'd say it's worth the bucks.

its not that the Timewave doesn't work, on 40 meters its a killer.
But 75 is a whole other issue. I think I either need to rethink
this process, either by making a sense antenna for 75 meters only
or relocating the current one to a different position and some type of
orientation/configuration which favors both. I almost think it might be
better to do a separate 75 meter sense antenna.

Equi is for equal, libra is the sign of Zodiac which is a pair of
scales

It means that a repetitive action must come back to its source.
AC power has a cycle as in frequency, thus its circuit is one
wavelength.

A quad antenna represents a one wave circuit where total length is
proportionat
to time .ie a picture of events during one cycle.
Now place along side of the quad a radiator of your choice where
the length of the short radiator is superimposed upon the quad.
For ease in foillowing the electrical circuit make your shorty
antenna
equal to one side of the quad

So the race begins. Both travel up for a time at the SAME velocity.
At the corner of the quad power travels onward until it gets to its
originating point to complete a cycle
The short antenna appears to have nowhere to go so what does it do?
To duplicate the quad action it must have a circuit of some sort where
the power can still travel forward during the time the power in the
quad
is still travelling to the originating point.

Complete the circuit of the short antenna showing the series of events
that occur upto the point that the events on the quad come to its
point of beginning.

Note The impedance of space is 377 ohms, the impedance of ground can
be your choice.
Art

Dear WA3YMM:

Which Tennadyne is on your list? Hard to beat for efficiency,
simplicity and bandwidth. The longer models (such as T10) appear to have
gain that is at least as good as a trap-beam.

In my opinion, having 18 MHz and 24 MHz coverage is valuable.

25 feet of un-guyed Rohn 25 is limited in the amount of wind induced
load that it can survive. If you are in an urban setting, or have a number
of substantial trees in most directions, you have a reduced chance of wind
damage. Do re-visit Rohn's recommendations.

Enjoy whatever you buy and get on the air. 73, Mac N8TT

but a wave comes back to it starting point after 1/2 cycle then reverses.
so why does your original assertion of a 1/2 wave 'gaussian' antenna still
hold? now, for a 1/4 wave monopole, where does the other 3/4's of a wave
come from?? and what happens to the power that is radiated? how does that
ever return to it's source to be in equilibrium? would a circuit that was
in equilibrium not be capable of radiating since everything has to return to
the source??

Hi Arthur,

OK, so now we see your work is taken from astrology, a variant of faith based science (aka superstition), but at least one older than Gauss.

Leave analysis of English to those who know the language - not the natives. ;-)

>AC power has a cycle as in frequency, thus its circuit is one
>wavelength.

So, for my AC powered oven to work at 60Hz, it must be resonant, or be at the end of a 5 million meter long extension cord. No wonder the price of copper is where it is. Did Edison or Tesla ever study Gauss - do you think?

Leave analysis of Science to those who know math - unless, of course, you can show a proof of how a fluorescent tube demonstrates equal Librium at twice the AC power cycle frequency of 60Hz.

[A gaussian theory that fails anywhere, fails everywhere.]

Oh dear I forgot to mention, there is another path for current flow
and that is at the center of the radiator. The impedance of this path
is lower than the impedance to space so naturally that is the path the
power will take.
Now on this inner path there are no electrons to dislodge as the
outer
electrons have decayed before they reached the center path so the
current
during this time is just travelling without supplying radiation until
it reaches the bottom of the radiator.
But it's counter part the quad is radiating during this time
(How about that experts!) And by the way it was mentioned somewhere
that the ground resistance was 2 ohms so one should now be able to
determine the IMPEDANCE of ground at the antenna base point
Now you take it from there....experts!

ah, the no electron anti-skin effect return path up the middle of the element. what about my elements that are hollow? where does the current flow then? or where does it flow in wire cage elements?? what about coiled elements like that 'new' short monopole, does it flow around and around inside the wire, or take a shortcut through something else? How does this fit into current wave reflection theory that easily explains the currents on elements complete with easily measured and well predicted values that don't require a return current up the middle?? too many questions left hanging art, you gotta work on that theory a bit more to fill in all the holes. oh, maybe thats it, try incorperating holes into your next version, maybe thats how the current flows back along the inside, it is the holes left over when the electrons 'decay'!

Ah. So even if it starts out in vertically polarized in Fort
Collins 'way out thataway (he says, gesturing faintly west-ish)
WWV's signal might be polarized north-north-west by the time it gets
ro Richmond.

> The fading in and out of the WWV signal you described in an earlier

Hm. Wonder if anyone has built an antenna whose polarization shifts
to "best match" the incoming signal? (No, not _this_ weekend!
<grin>!)

> I haven't followed the thread closely, so please pardon me if I've

A minor update: It seems that I was _mis_tuning my antenna,
adjusting it for the strongest signal (highest stack of LEDs lit).

Over the past two days either I've finally tuned it _correctly_ or I've done that _and_ the signal has improved. Whatever the cause(s), I can now -- at times, in fact for an hour at a time -- hear the tocks fairly clearly and even understand the voice. (Who knew the announcer's phrase for UTC "Coordinated Universal Time"?).

How good? Well, I've unplugged the clock to reset it and it has then received an "acceptable" WWV signal (it started showing digits) eight times in the past two days. It might have been more times, but I don't watch it constantly, and I've noticed that twiddling the tuning knob tends to make sync-ing a little harder. ("Ack! It's fading! See if I can tune the antenna _just_ a little better!" <grin!>)

I _do_ know that the point of best reception is much narrower that I thought it when I was tuning in that "other" signal. Turning the tuning capacitor's knob a "minor wiggle" either way can decrease the signal strength by an LED or 2, and I need to compensate for the effect of moving my hand near the antenna to tune it. <grin!>.

Oh, and the MAC-II seems to be a lot pickier about what it will and will not accept than my ears are. The microprocessor is driven by a 9.216MHz crystal and it's an 87C52 (an 8051-alike) which (as I recall) means it only gets around 0.768 MIPS (clk/12) to do all its work, so I doubt it's doing much "DSP" itself; its interrupt lines are tied to a 567 tone decoder IC for WWV's "start of minute" and BCD data subcarrier tones (1000Hz and 100Hz).

The MAC-II seems to be very "picky". Part -- but not all -- of its requirement for starting the clock digits running is that it receive a recognizable 100Hz signal for a full minute, that is, between one 1000Hz tone and the next. In other words, if WWV's signal is fading on a 5- or 30-second cycle, odds are good that at one point the signal will be come "bad". I've seen it recognize the start of a "frame" by lighting its CAPTURE LED, but then turn it out ten or forty seconds later when part of the frame has faded a bit; my ears can still recognize the tones, but the're better designed and have a better processor than the MAC-II<grin!>. This pickiness I suspect is part of the reason it takes to long for the clock to start running.

> directions can be something of a project.

I do a lot of reading in comp.dsp (sometimes it's fun just watching the phrases fly back and forth <grin!>), and one common topic there is the difference between "noise" and "signal". For me, "signal" is "what I want", "noise" is "everything else", and the fun(?) part is figuring out how to get as much of the former as I can while downplaying or being able to ignore the effects of the latter. My next step is to add a "line out" jack to the MAC-II so I can capture long stretches of the signal to disk; when reception goes bad again I'll be able to use Scilab or Matlab or something to play "Beat the Heathkit!" with my own algorithms.

And if I get tired of that, I can unsolder the 87C52 and wire in one of Atmel's $20 Butterfly boards in its place, adding an LCD and my own algorithms. And _then_ I can... and _then_ I can... <grin!>

Anyway, "It's feeling _much_ better now." <grin!>

If you're reading these posts in the same order I'm posting, you'll
have already read my good news:

It's Working!

(Oh. That's right -- this is Usenet. Y'all can't here the
"doooonb"-ing from down the hall. Well, take my word for it -- or
even the MAC-II's display! <grin>)

This doesn't prove that the MAC-II's J-FET RF amplifier hasn't been
degraded through an... er, "very wideband RF overload" <grin!>, but
I think it does say that "completely fried" is unlikely (which
pleases me greatly! <grin>).

My earlier MAC-I had a nice whip built in, and could select the
strongest signal among (IIRC) 5, 10, and 15MHz, but it had the same
problems getting an "acceptable" WWV signal most of the time.

Well, you have a reasonable _presumption_, anyway. <grin>

In _theory_, one could have two clocks in error and one on time. Or
even all three out of step with (say) the NIST's clock. But
two-out-of-three would be the place to put your money. <grin>

I can believe it. I've seen those LCD "clock and weather" stations
take days to synchronize the time (I assume they're using WWVB).
OTOH, I'm hardly one to talk, since I've let the MAC-II sit
liostening for months at a time without successfully locking-in on
WWV.

If I'm following the ARRL handbook correctly, I want the elements
laid out _across_ the incoming wavefront. For Fort Collins to
Richmond, that is, going west to east, that would mean I'd want to
string the wires/elements north-south. Naturally (per Murphy, the
patron saint of Data Processing) my house is oriented E-W. Which
does still, as you point out, leave the possibility of building
something outdoors.

Still, my current indoor loop seems to be picking up a nice strong
signal. It was upright when I first started testing, but it wound up
being laid flat at some point in the past few days -- about the time
I discovered that I had been mis-tuining it. Wonder which had more
effect: my changes, or atmospherics? <grin!>

Anyway, thank you for your time and suggestions. I did some looking
around on the 'web for introductory material to help me understand
the ARRL Antenna Handbook and stumbled onto these:

Antenna Newcomers and the Language of Antennas
http://www.cebik.com/tales/nc.html

Antennas from the Ground Up
http://www.cebik.com/gup/groundup.html

Some really nice propagation plots. Now, if there were just some
simple way of figuring out which way the antenna is oriented
relative to the plots... "It's an imperfect universe" <grin!>

My current box, the MAC-II, only monitors 10MHz; its predecessor,
the GC-1000 MAC, monitored (IIRC) 5/10/15MHz and chose the
strongest.

Thanks for your signal report and the antenna suggestion. I'll keep
it in mind.

On the other hand, my tuned (and currently horizontal) loop is
suddenly picking up WWV/10MHz remarkably reliably, and I didn't even
have to "sacrifice a goat at midnight"! <grin>

Has your reception improved lately as well (last few days)?

The RF section is a one-transistor (J-FET) amplifier followed by a
TDA1072A "Integrated AM receiver" chip. I'm not sure how to go
about comparing that to your equipment.

Highly possible, but the noise level "at the speaker" seems to have
fallen off appreciably in the past few days. Also, I think I'm
doing a better job of tuning the antenna; adjusting with no clearly
defined signal is a chicken-and-egg problem, but two days ago I
started hearing a deafening cackle. <grin!>

Yup. GPS would eb the way to go for accuracy... or -- for the
billion-dollar-budget people -- your very own Cesium Clock. <grin!>

Let's now proceed with that analysis...

Libra (actually the postfix of equilibrium is Librium, a drug used in the treatment of anxiety disorders), when we divorce it of the nonsense science of astrology (there is lot of nonsense going around this topic), Libra is a fairly common root word found throughout Europe having emerged from the Roman empire. Nearly every context of Libra is with weight, and means "pound." Any Englishman would know this, of course, given the obvious correlation to ï¿½. Odd thing is that the Roman pound (a libra) is closer in weight to a Kilogram than it is an English pound (in weight, not cost).

However, I was brash to dismiss the faith based science of astrology, and in an effort to be equilhanded, we should proceed to the meaning of Libra in that context:
"Social consciousness. Affableness. Love of Beauty.
The longing for comradeship. Sympathy. Justice.
Spiritual devotion."

Historically, astrology has been used to justify selling missiles to Iran to obtain funds to support the failed "patriots" of Nicaragua - so it comes as no surprise that it should pollute the idiom of RF.

Thank you Arthur for giving me the opportunity to set the vocabulary straight,

[In a grand jesture of Librality, no emails were harmed through inaffable violations of private spiritual devotions being disclosed within this analysis.]

Well now David thge charge has arrived at the bottom of the radiator.
It is now in a quandry
it looks over at the quaud and ssees that the charge over there is
half way around!
So the charge on the small radiator finds that it can only go up
aqgain forming a loop of current.
Fortunately it is now back on track radiating just like the quad.
Ofcourse when he gets to the top
it again has only one place to go and that is down the center again
where it can't radiatiate
like the quad is doing.When the charge gets to the bottom it wsees a
path of 2 0hms (the resistor)
so it passes thru the resistor where the charge finally gets back to
the starting point at exactly the same time that the charge of the
quad got back home.
So the sequence of events is that the short antenna only radiated half
of the time neglecting the travel thru the resister of course. So the
quad radiated twice the time of the smaller radiator which amounts to
a 3 db gain.
Well some might say we knew that a quad radiated more because it is
the same as two dipoles(half wave) on top of
each other so yes for the same power expended in the same amount of
time a full wave radiator radiates twice the power that a quarter wave
does.
Art you are a genius put QED at the end of this post and also get hold
of Yuru so that he now can get to sleep at night.

Now with respect to the current loop formed on the short antenna.
This loop defies the existing conception that a short radiator
is a series circuit but instead it is a parallel circuit ala tank
circuit mode
Where the energy sinks explode such that they put electrons in a orbit
mode as they travel because of their tenacity with respect to their
initial
resistance to motion(inertia)as they lay dormant on the outside of a
diagmatic material.
Diagmatic material is a material that will allow an electron to rest
on it's surface
without being combined into the basic material that consists of an
atom and a lot
of other stuff that is in orbit and in equilibrium of itself.
Note that the electron that is now in orbit and is not polar, thus it
is not
affected by gravity on its travels on it's way to find a suitable
resting spot
(diagmatic surface)which can also be outside the earths sphere of
presence and
come to rest on another planets surface in the same way that moon
dust occurs.
NASA has had some success of blowing the moon dust off of material by
mimicing
a tank circuit using just one energy sink release where they were
able to remove
half of the moon dust or overcome it's inertia. Apparently they do
not want
this dust transported to the space vehicle. Note that while in

rotation the electron
posseses both weight and energy where the latter does decay over time
though its
weight stays dormant.Note that a diagmatic material has lots of
"spare" electrons
that imediately take the place of removed electrons and where it
prevents the
resetlement of electrons that do not escape the arbitary field around
the host
material forcing the returning electrons to reside under existing
surface
electrons to form a "skin depth" where they eventually decay.
Enuff said.
Gauss was on the right track when he decided to work at the
observatory.
Pity he didn't delay things and apply a time varying field to
accompany
his law on statics. But no worries a hundred years later along came
Art.

Gentlemen
I tuned my antenna this afternoon for 1.9 Mhz where the S meter was
regesting S9 noise.
Put a sheet of aluminium under it and the noise stayed at S9
Now I need to put a sheet of aluminium on the top of it to form a
capacitor
but that I can't do by myself as I need another pair of hands to rest
it on the top.
Hopefully my niehbor will show his face sometime in the next couple of
weeks so I
can complete the experiment. I made the antenna as large as I could
so when
it is inbetween the two 8 X 4 sheets I will see a difference in
signal.
Time to mow the grass for the last time and empty the gas tank for the
winter.

If you guys have each others email addresses why are you posting all of your private correspondance here ? Just wondering, because it isn't contributing anything to the discussion of antennas which is what this newsgroup is all about.

i am convinced that art is playing dumb on purpose.... no one with any knowledge of antennas and em fields could possible get this screwed up on basic concepts. when he was just talking 'gaussian' and 'equilibrium' stuff it could easily be laughed off as someone with a little bit of knowledge trying to force the rest of the world into that single concept. but now with decaying electrons and current down the center of the conductor and a missing half cycle its just too far gone. i had been kind of tagging along tweaking him into trying to explain the details of his concept, but now it is apparent that he has none. he is just making it up and stringing us along. you gone too far this time art, ciao and enjoy your game alone.

Good Day all!
Now I have my Kenwood ts-820S going on TX again I must turn my attention to another problem.
This is entirely a result of my house and section layout.
I have a G5RV antenna supported by a 7.5 metre mast in the centre on a quite steeply sloping section.
The antenna runs East/West. Now thw western (high) end is supported by my upper fence posts on top of a timber retaining wall totalling about 4 metres AGL. The antenna wire is substantially horizontal at that end.
The eastern end however has the problem of a mast of any greater than 3.5 metres high interfering with our neighbours view and they are very good neighbours!
As a result the eastern end of the G5RV slopes down at about 20 degrees and is only 3.5 metres AGL at the end.
Now I have noticed that my "Z" match antenna tuner is much more critical in adjustment than it used to be with a horizontal G5RV at my previous QTH.
Obviously the capacitance to ground will be very different between the 2 sides of the doublet and I have a fair amount of mains borne QRN here. Has anyone else sorted this problem, it will not be easy to move the antenna as my section is only 860 M2.

The eastern end however has the problem of a mast of any greater than 3.5 metres high interfering with our neighbours view and they are very good neighbours!
As a result the eastern end of the G5RV slopes down at about 20 degrees and is only 3.5 metres AGL at the end.
Now I have noticed that my "Z" match antenna tuner is much more critical in adjustment than it used to be with a horizontal G5RV at my previous QTH.
Obviously the capacitance to ground will be very different between the 2 sides of the doublet and I have a fair amount of mains borne QRN here. Has anyone else sorted this problem, it will not be easy to move the antenna as my section is only 860 M2.

Locking in 8 times in 2 days is probably pretty good

Not sure what you are tuning but best signal to noise ratio is not always
synchronous with greatest gain.

Awe common Dave don't go away this is fun! Now what is wrong with
current
going down the center because the impedance is less than 377 ohms?
Remember if you go up in altitude the 377 impedance will go down and
become
less that the wires internal impedance the energy will transfer to
space with
that smell of ozone. That is what happened in Quito Equador
That is what led to the design of the quad where a
lesser impedance path was provided for current flow!
Now the inner impedance of the wire must be pretty high to
create an end effect so with Isq R there has to be a lot of
heat generated. Remember Vincent saying his first antenna melted?
Now we come to rotation of a projectile.
Did you know that a projectile tumbles and comes under the influence
of the Corrioli effect as it losses energy.A shell
starts to tumble when it exceeds it's range Next time a rocket goes

into space watch for rotation. What do you think causes that?
A train speeds along on a railroad until at a certain speed
it will roll over, why do you think that happens?
Look up "hammer blow" for that one. How can
I possibly be stringing you along?
You can put everything to bed by spending
a 1/2 hour making a full wave antenna but ofcourse that
means an effort to get off the couch !
Yup
It is better to stay rested and let your mouth do
all the work at least until you start to dribble.

Not exactly. The wave will still be nearly planar, that is, the orientation of the E field will be in a plane which is perpendicular to a line between you and the effective point in the ionosphere where the wave is coming from. But the E field can be rotated in any direction within that plane. So you want your antenna to have substantial gain in the direction of Fort Collins and at the elevation angle of the arriving signal (the latter will vary somewhat). But the polarization is a crap shoot.

>
> Hm. Wonder if anyone has built an antenna whose polarization shifts
> to "best match" the incoming signal? (No, not _this_ weekend!
> <grin>!)

Sure, many. Polarization diversity is an old idea. In a previous life I worked on a phased array radar (cf. http://www.globalsecurity.org/space/systems/an-fps-85.htm). The transmitters have only horizontal dipole antennas so they transmit only a horizontally polarized signal. But each of the 4660 receivers has two dipole antennas, one vertical and one horizontal. This gives the receiver information about whether an object is tumbling or rotating, for example, by the way the polarization is shifted by the reflection. Amateurs would have to use polarization diversity at both ends of a contact, since there's no way to predict which polarization would be best at a given moment for transmitting to a fixed polarization receiving antenna.

Be cautious in generalizing about your accomplishments. Day-to-day propagation differences can be extreme. Unless you can do an immediate A-B comparison or take many, many measurements over a very long period of time, there's no way to distinguish between antenna and propagation changes.

The whole objective to receiving system design is to maximize the signal/noise ratio, where "noise" is "everything you don't want". Making both larger by the same amount accomplishes nothing you can't do with a simple amplifier.

You're following it correctly only if you're using elements which are no longer than about 5/4 wavelength. The direction of maximum gain isn't longer perpendicular to the wire if the wire is longer. This is covered very will in the _Antenna Book_.

You can duplicate the plots for the kinds of simple antennas you're dealing with, with the free demo version of EZNEC available from http://eznec.com. In the View Antenna display, select View/Objects, then check the "2D Display" box. Then you'll see a 2D plot superimposed on the view of the antenna, to show how the two are related. When viewing a 3D plot, the View Antenna display rotates along with the 3D pattern, so you can see how they're related if you keep both windows open.

Normally WWV rxceivers have there antennas tilted at 45 degrees in an attempt at polarity diversity. Im not sure if the department store clocks do anything like this. The only one I have ever seen used a loopstic antenna. The professional grade rx I am familar with that was used to set the time on a computer used a contuously loaded dipole on an outside mount with 45 degree polarization.

Chuckle

Tilting would work fine if an incoming wave couldn't have any polarization except vertical or horizontal. But it can -- it can be at any angle. So it doesn't matter how you tilt the antenna, the probability of the incoming wave's polarization being aligned with it, at right angles to it, or having any other relationship to it, is the same as for any other tilt. (For simplicity, I'm ignoring the fact that the probability of a wave arriving with a particular polarization angle varies with the elevation angle when ground reflection is involved -- which it virtually always is with HF skip propagation.)

A 45 degree tilt might be useful if you were receiving a line-of-sight signal which might come from either a horizontally or vertically polarized antenna. But even then, if the transmitter's antenna was tilted 45 degrees the other way, you'd be cross polarized and in the same boat as if one were horizontal and the other vertical.

One solution is a circularly polarized antenna, which responds equally well to linearly polarized waves at any polarization angle. However, there are a few problems involved with that. First, it's difficult to get circular polarization from an antenna when ground reflections are involved. Second, most of the simpler circularly polarized antennas like a turnstile are circularly polarized in only one or two directions. For that antenna, for example, the polarization is elliptical at other azimuths and elevation angles, and linear to the side. And finally, it seems to me possible that ionospheric propagation can cause a received signal to be elliptically polarized even though it's linear when it's transmitted. I don't know if this is the case, but if it is, it guarantees that even a circularly polarized antenna would experience fading from polarization shift. Of course, even if you completely eliminate fading from polarization shift, you still have to deal with multipath.

Hi Art,

It's a dawgone shame that the electronic wizards on this thread don't have a clue that you're pulling their
legs with your humorous anecdotes concerning the clever antics you have the electrons engaging in. I don't
know the acronym to tell of my response in shorthand, but I'm rolling on the floor in hysterical laughter at
your brilliant forays into your comedic repertoire.

Art, I assume yer retired, and may have somewhat of a nest egg to support the lifestyle yer accustomed to, but
let me tell ya, yer missing a golden opportunity to multiply that nest egg exponentially. How could you do
that? Well, ya know there's Leno, and there's that Dave what's-his-name, Oyeah, Letterman, and they both need
writers for their one liners, who are becoming stale lately. They could use your comedic talents if they plan
to stay in their present jobs. And then there's also Jimmie Kimmell, who's really going places. Just think of
how much faster he'd get there if you were writing for him!!!

Art, with all yer talent yer wasting yer time tryin' to fool the wizards on this thread, cuz they just don't
get it. They're all wound up so tight trying to explain to you how electrons radiate that they don't know that
all yer writing is fer comedic entertainment that's apparently going right over their heads.

I'm enjoying every minute of your entertainment presentations, and I'd miss them dearly if you left the
thread. But your talents would be much more appreciated if your writings were to be presented to the national
TV audiences, on whichever channel you choose to present yer work.

Sincerely yers,

Walt, W2DU

snip
Doesn't a circular polarized antenna lose 3 db when responding to
linearly polarised waves?
IF that is the case it doesn't "respond equally as well"
As far as 45 degrees goes that is not correct for maximum response,
more likely a 45 +- 11 degrees would supply the most gain.
Kraus refers to this empirical tilt action in his chaptor on helix
antennas
which I now see as the summation of all radiator vectors when
expanding Gauss.

Like I said it was an attempt, reccomended by the manufacturer of the rx no
less. I always got a chuckle out of it too, every time I saw it. A member of
our engineering staff went into a long spiel about why it should be mounted
at 45 degrees. Thats when I asked him what college he attended because I
didnt want my kids going there. A few days later he sent me an email
apologizing and admitted I was right that it really doesnt matter which way
its turned.

Hello,

I have some problems with an Elektro-Automatik EA 3011 12V/10A power
supply. Does somebody own the circuit diagram of this power supply?
It saves me a lot of time from extracting it from the PCB.

Best regards,

Wim

Art could really know better, and might be posting what he does as some form of personal amusement.

The only problem with that is some readers of his posts may think his posts are accurate, unless others who know they are not make the effort to post the correct information.

Source record: 35395

I am seriously lusting over the concept of putting together a foursquare array of 40M verticals.

I found the http://www.zerofive-antennas.com/ website and the antenna part looks do-able. If a bit heavy-duty!

I think I have the space in the yard to put down the radials. The house gets in the way of one direction but I think I can put down at least quarter-wavelength radials from each base in all directions and half-wavelength or longer in some other directions.

I have some old ARRL antenna handbooks with articles by Roy Lewallen about phasing arrays and measurements. I also have EZNEC. Is there something I can do to prove to myself that having my house on one side of the array and the edge of my lot on the other side of the array, resulting in a radial plane that's not radial but more like a rectangle, won't mess up the whole concept?

And if I draw things out it looks like an 80M foursquare array would be possible but my house would be in the middle of it :-). Is this a recipe for disaster or would it actually work? (Not that I could afford four 75-foot vertical radiators from zerofive, but I can imagine!)

Tim.

Yes, such things have been built. There are some French researchers who built an adaptive combiner that combined multiple polarizations, and also did the processing to allow using both the ordinary and extraordinary ray, and substantially improved link reliability on 1000km skywave paths.

UTC is not an acronym. It's a madeup identifier that matches neither the English (Coordinated Universal Time) or the French (T U C.. I won't even attempt to figure out what it is..).

These sorts of international metrology things have all sorts of such negotiated compromises in them, stemming all the way back to the Prime Meridian being in Greenwich, but measuring in meters.

Hi Tom,

Radials, on/in the ground, do not need to be fractional wavelength
multiples (eighth, quarter, half...). Length = radiator height is
fine, shorter and more is roughly equivalent.

>Is there
>something I can do to prove to myself that having my house on one side
>of the array and the edge of my lot on the other side of the array,
>resulting in a radial plane that's not radial but more like a

No, probably not. And if it proved anything, what could you do about
it anyway?

>And if I draw things out it looks like an 80M foursquare array would
>be possible but my house would be in the middle of it :-). Is this a
>recipe for disaster or would it actually work?

No, not a disaster. It probably might/might-not work.

Radials are for matching and efficiency. They do impact lobe shape,
but in the scheme of things (a four-square) you are already managing
that detail and the lobe offsets probably average out anyway.

What I mean is that if you located each element in the corner of your
lot (hypothetical, as set-backs for neighbors and guying will probably
force another configuration); then you would have a radial field at
each one that could only fill 90 degrees of the circle expected at
each (for a pristine, factory guaranteed installation). The lack of
3/4ths of those radials would bring loss. The lack of 3/4ths of those
radials would reduce signal strength in those un-radialed directions.

However, you have three others that do point in those directions
filling in all 4/4ths - as an average. You still suffer the ground
loss, true, but the ground coverage you do have probably stiffens the
system sufficiently to exhibit the expected beam forming - I presume
this is the feature you are after.

>even attempt to figure out what it is..).

Hi All,

In fact, UTC is an acronym (already anticipated by Frnak and
explicitly stated every minute). It is but one of several, this one
being rather genericized (because any longer would force a lot of
talking, and minute passes by pretty quickly). The others would
include: UTC(NIST), UT1; and the academic UT0, and UT2.

The reason for the initials order is that there is an hidden comma.
Universal Time, Coordinated. Wikipedia reports this as an erroneous
expansion, but Wikipedia wasn't there in my Metrology classes (a
couple dozen miles from NBS) where we worked with these NBS standards.
It wasn't there when (1974) I performed the second leap second on my
Cesium Beam Standard which was calibrated through WWVB (taking about
half an hour, part of which was waiting during the roughly 15 minute
intervals between TOCs). My antenna was so far away (on the fantail
of the ship in another "time zone"), that I had to slip the time by
100nS.

Knowing that Arthur only reads his own threads, I won't have to
anticipate his rejection of the following efficiency reports for a
non-gaussian antenna. From NIST (the people who know efficiency)
about their 60KHz antenna system:

"Each antenna is a top loaded monopole consisting of
four 122-m towers arranged in a diamond shape.
A system of cables, often called a capacitance hat or
top hat, is suspended between the four towers.
This top hat is electrically isolated from the towers,
and is electrically connected to a downlead suspended
from the center of the top hat. The downlead serves
as the radiating element.

"Ideally, an efficient antenna system requires a
radiating element that is at least one-quarter wavelength
long. At 60 kHz, this becomes difficult. The wavelength is

5000 m, so a one-quarter wavelength antenna would be 1250 m tall, or about 10 times the height of the WWVB antenna towers. As a compromise, some of the missing length was added horizontally to the top hats of this vertical dipole, and the downlead of each antenna is terminated at its own helix house under the top hats. Each helix house contains a large inductor to cancel the capacitance of the short antenna and a variometer (variable inductor) to tune the antenna system.

"Using two transmitters and two antennas allows the station to be more efficient. As mentioned earlier, the WWVB antennas are physically much smaller than one quarter wavelength. As the length of a vertical radiator becomes shorter compared to wavelength, the efficiency of the antenna goes down. In other words, it requires more and more transmitter power to increase the effective radiated power. The north antenna system at WWVB has an efficiency of about 50.6%, and the south antenna has an efficiency of about 57.5%. However, the combined efficiency of the two antennas is about 65%. As a result, each transmitter only has to produce a forward power of about 38 kW for WWVB to produce its effective radiated power of 50 kW."

Finally got the aluminium sheets secured and now I have to find a
microphone
so I can work some low power over the next two weeks.
I am anxious to see if it will duplicale the bottom antenna of a stack
where
the capacitor/antenna bleeds off noise to the ground.
Antenna will stay sitting on the ground until I get a feel of how it
reacts in the coming days of showers.
It is set up as a cloud burner at the moment so I should get some
contacts.
All bands seem to be active so I will put a chair in the yard and play
Maybe even take a photo for the record!
Plenty of harmonics so most bands should be available

The NIST folks could probably increase the efficiency to greater than 90% if they dug a large pit to temporarily store the decaying electrons. All of those dying electrons lying on the ground tend to discourage the active electrons from working as hard as they could.

The efficiency could be raised to nearly 100% if the two helices were wound in opposite directions. That would provide the best shot at equilibrium.

Don't know about WWV in particular, but this past weekend on the ham bands there was an obvious uptick in propogation conditions. The MUF was up enough that I heard several pileups on 15 meters and 40 and 30 Meters were more hopping than usual in mid-day/early evening.

Tim.

Hi Gene,

You shave points too close. They could achieve 130% efficiency if
they simply tapped into the current return on the inside of the wire.

Arthur's 3dB here and 3dB there, if you use enough wire, then you are
beginning to talk about GAIN!

Also, Fort Collins is a higher altitude than Podunk Illinois, so
impedance is less than 377 Ohms too! High gain, maybe 129% efficient.

***** irony mode off ********

Load resistance seen by the transmitters is roughly 0.85 Ohm
transformed to 50 Ohms.

Hi Cecil, Looking at your webpage, looks to me like a 103' dipole with 36-j324 impedance at 3.8 Mhz needs 28' of 450 ohm line instead of 300 ohm. 28' of 450 ohm line put you at 24+j25 with an swr of 2.7:1. 1000pf shunt cap. puts you near 1:1.

As for modeling the Shunt Capacitor, I have never done it, but you might try a stub to simulate the Xc. Don't have time at the moment, or I would give it a try.

I wasn't trying for perfection, just improvement. I actually
tried it on my G5RV and got considerable improvement in reality.

With EZNEC v. 4.0 and earlier, the only way to model a shunt load other than a short stub was to make a small triangular or square loop and put the load on one leg and the parallel object on another leg. If the loop is too small, NEC will have trouble with it; if too large, its reactance will affect the result. Sometimes there's no suitable size.

Which is why I added the new parallel connected load feature to EZNEC v. 5.0. In that version, it's simple. The rightmost column in the Loads menu grid is "Ext Conn". Enter "P" or "Par" in that column, and the load will be connected in parallel with any other object on the same segment. See "Load, Parallel Connected" in the EZNEC v. 5.0 manual for more information.

Au contraire...
while UT1, UT0, and UT2 are, in fact, acronyms of a sort, primarily
based on astronomical time, this is not the case for UTC..

the coordination has to do with matching up UT and TAI (atomic) time..
all those leap seconds, etc.

As one online source puts it:
The (Bureau Internationale de l'Heure) BIH was charged with the task of
monitoring and maintaining the program and introduced the term Temps
Universel Coordinnï¿½ or Coordinated Universal Time for the coordinated
time scale in 1964.

BIH is the predecessor of the current BIPM (who seem to have a problem
with the standard kilo losing mass) http://www.bipm.org/

or, for more information:
http://syrte.obspm.fr/journees2004/PDF/Arias2.pdf

which says: The name of Coordinated Universal Time UTC appeared in CCIR
documents in the early 60s.

One might also seek a paper from 1964, by Guinot. (who was a time guy at
the BIH back then)

A paper by Dennis McCarthy at USNO on "Evolution of Time Scales"
mentions in Section 6 that: the term "Coordinated Universal Time" was
introduced in the 1950s to designate a time scale in which the
adjustments to quartz crystal clocks were coordinated among
participating laboratories in the US and UK.

A more recent paper by Guinot says:
"Until 1965, the more or less common scale for emission of signals,
which had received spontaneously the name of Coordinated Universal Time
(UTC), had not been strictly defined."

>
> The reason for the initials order is that there is an hidden comma.

Funny, thing, though, that if one searches the literature of the time
for that particular sequence of words, it never occurs..

Given that Coordinated Universal Time existed well before UTC, I suspect
that the comma thing is a post hoc creation.

Wikipedia reports this as an erroneous

Would it affect the performance of this antenna if I spray painted (LIGHTLY) the red coils? I'm try to "tone down" the redness and maybe lightly spray over the coils with a green or brownish color so as to make the coils less visible. I would cover the contacts and the ends, just lightly spray the coils.

Could spraying those coils lessen performance?

Not everything is English, folks. UTC is for Universale Temps Coordinaire. No comma is implied or needed because in French, an adjective follows the word it modifies, with very few exceptions.

You are writing to one who read the literature - at that time. My
experience is not from arm chair history 101. UTC was arrived at as a
compromise between the French (naturally) and the "rest of the world"
(what else?). My bona fides are documented too: two diplomas from the
only Metrology school in the United States - at that time. Time in
service: with training in calibration and maintenance of the HP Cesium
Beam standard, and VLF subsystem - at that time. I also lived through
the great switch-over from cycles to hertz, and GMT to Zulu - at that
time (or slightly before... I wasn't looking at the clock that day).

I can flood this page with 250 references that employ the strict usage
of "Universal Time Coordinated" "Universal Time, Coordinated" or
"Universal Time (Coordinated)" and specifically 35 of them printed
before 1967. With google it takes more time to cut and paste than
actually find them. A short list includes:

Title 15 1971 Code of Federal Regulations By United States Office of
the Federal Register (1971)
"... the Universal Time Coordinated (UTC)
system' as recommended by the Bureau
International de l'Heure (bill).
The carrier offset currently is minus 300 ..."

2380. Question on dipole SWR problem

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-16 01:00:49 UTC
From: Ed G <Huckleberry_REMOVE_@bigvalley.net>
Message-ID: <Xns99CAB742B368HuckleberryREMOVEbig@198.186.192.196>
Source record: 35412

Our ARES station has had a NVIS antenna on the roof of the building we are in. It is a large, one story structure with a rubber coated on steele roof.

The dual dipole type antenna, center at 14' and ends at about 3' high, was fed with a long run of coax and has historically exhibited a large SWR when operating below about 3825 KHz.

We recently replaced the entire antenna assy with a 122' half wave dipole, fed with 600 ohm ladder line to an SGC antenna coupler at the base of the center mast. Heights are the same as previous.

The SGC 237 coupler tunes the antenna well above 3825, and all other bands, too. However, we still exhibit a very high SWR when going below about 3825 and the tuner fails to tune... in fact the Radio's power drops way down, possibly preventing the tuner from working properly. A different radio shows the same problem.

QUESTION: Can anyone offer reasons we may be having this tuning problem below 3825?

Thanks.

Ed K7AAT

I ran EZnec on it, and the impedance at resonance is about 5 Ohms (at about
3.8 MHz). Most of the energy goes straight up, which might not be bad for
local contacts. If you have your heart set on it, try a 9:1 balun at the
feedpont.

Not surprising with a dipole located that close to a counterpoise. The
feedpoint impedance should be pretty low, I would guess 10 ohms or less.

The meter simply measures the ratio of the power travelling along a feeder line to an antenna against the reflected power back from the antenna and feeder due to a mismatch of impedence.

The VSWR meter does not strictly need to be calibrated. Simple meters tend to be frequency sensitive and are provided with a control to adjust the meter to read full scale for forward power. Operating a switch or reversing the connections allows reverse power to be assessed.

A VSWR meter will also only read accurately if the impedence of the antenna and feeder system is the same as the design impedence of the metrer, usually around 50 ohms.

More complex measurement circuitry and sensing devices can be used to compensate for frequency sensitivity and the meter calibrated against known loads in a factory. The important thing is to know how much reflected power is in the system because this power largely ends up being dissipated as heat in the transmitter final stages.

Let me second Richard's comments about radials needing to be some specific fraction of a wave - not....
Just put down the radials you can manage... If it isn't a perfect circle around the antenna, don't even think about it, put the radials down and enjoy your antenna..
Don't measure them, just pace them out from the antenna, cut and secure the end, step sideways, secure another end and pace back to the antenna, repeat... Whatever you get down will work...
Read, K3LR's comments about putting up a low 160 inverted L for an impromptu contest while on vacation, having just two 1/4W radials and working 40 some states and a bunch of countries...
So, assuming you can get down 20 or more radials under each vertical, the 4 square will work...
If you could get down lots more radials the 4 square will work a bit better on weak signals (strong signals won't notice how many radials you have down)
If you could get down 120 'full wave' radials, the 4 square will work the very best it can be (roughly 2 ohms series resistance on the ground circuit)...
But after 50 radials of random length, you will be hard pressed to tell any difference between that and the 120 radial 'perfect' ground plane...

cheers ...
denny/k8do

ilu.arunkumarc@gmail.com wrote:
> Why calibration is required for VSWR meter...

Assume 100 watts in a 50 ohm transmission line
driving a 50 ohm load. The current in the line
is 1.414 amps and the voltage across the line
is 70.7 volts. That's also the current through
the load and the voltage across the load.

A typical SWR meter samples the current using
a toroidal transformer function resulting in a
sample voltage proportional to the *line current*
and equal in phase. Call this phasor voltage V(i).

The line voltage is sampled through a voltage
divider. The result is a sample voltage proportional
to the *line voltage* and equal in phase. Call this
phasor voltage V(v).

To obtain a voltage proportional to the reflected
power, the two sample voltages are subtracted, i.e.
added out of phase, so the total voltage,
V(t) = V(v) - V(i) = 0 for zero reflected power.

The only characteristic impedance and load for which
V(v) = V(i) is Z0=50 ohms. If one increases Z0,
V(v) will increase and V(i) will decrease and not
be equal in magnitude. If one decreases Z0, V(v)
will decrease and V(i) will increase and not be equal
in magnitude. Thus the SWR meter is calibrated to
50 ohms and only 50 ohms. If we switch to 75 ohm
coax and a 75 ohm load, the 50 ohm SWR meter will
indicate reflected power where none exists on the
Z0=75 ohm line.

(One can argue that the reflected power within the
50 ohm meter actually does exist inside the Z0=50
ohm meter environment but that is another discussion.)

An SWR meter is essentially a bridge with one leg
of the bridge typically set to 50 ohms. I have
designed SWR meters to read forward and reflected
power calibrated for Z0=300 ohms and 450 ohms. Those
meters are not useful when used with coax.

Continuing: To obtain a voltage proportional to the
forward power, the two sample voltages are added in

phase so the total voltage
V(t) = V(v) + V(i) = 2*V(v) = 2*V(i)
for the forward power indication in the example above.
A 100 watt calibration mark is written on the meter face
for that condition above.

If one goes through the exercise of the current being
out of phase with the voltage, one will observe that the
forward power and reflected power readings are accurate
as long as Vfor/Ifor = Vref/Iref = Z0 = 50 ohms.

V*I*cos(theta) = forward power - reflected power

It occurs to me a bandaid fix might be a 4:1 balun. Just hook it up
backwards; that is the 200 Ohm side to the tuner and the 50 Ohm side to the
antenna.

Hi Ed,

I assume that the metal roof extends over the full length of the
dipole.

Your antenne is very close to ground, that results (as mentioned by
other posters) in a very low radiation resistance (about 5..10 Ohms).
When using this construction at 40m, the impedance will be very High
(certainly above 6 kOhms, when losses are low).

I would recommend you to raise the antenna. This increases the
radiation resistance at 80m significantly. This lowers the impedance
at 40m also (making it easier for the tuner, resulting in higher
overall radiation efficiency).

When raising the antenna is not possible:
Construct the quarter wave sections of about 3 wires in parallel,
about 1m separated. Connect the wires at the feed point. This
"emulates" a thick strip dipole.

The result is that the radiation resistance at 80m does not change, but the input impedance at 40m reduces significantly (a factor 6 is possible). This enables the use of a transformer (for example 2(feed line) : 1(dipole side)). Now the 5..10 Ohms becomes 20..40 Ohms and the 6 kOhms will remain, or drops a little. As the impedance ratio has been reduced now, matching is easier. Please note that your transformer experiences high voltage (so high core flux) when operated on 40m.

Other option: use the transformer on 80m only, and remove it (relay) when operating on 40m.

I hope this helps a bit.

Best regards,

Wim

I defer to your googling skills..

I tried the search above, turned up nothing (other than obvious
derivative works like the wikipedia entry) in the first 10 pages of
hits, and took the references from BIH as definitive.

(I also tried WebOfScience, etc.)

I also didn't trust references from post, say, 1970, because by then,
you'd have seen definitions created by "back-formation" (i.e. finding
words that match the acronym.. which, when it comes right down to it, is
how lots of acronyms get created in the first place)

>

> Proceedings of the IEEE. By Institute of Electrical and Electronics
> Engineers (1963)

Looked for this one, and couldn't find it. Which month?
The oldest paper in Proceedings that has the term "universal time" in it is Hudson's paper in June 1967, p815 ff

It refers to CCIR recommendation 374.1 and CCIR reports 365 (in 1965) and 366 in connection with the discussion of UTC and SAT, but doesn't actually define UTC, nor does it provide a reference to a defining source. (other than a "in press" paper by Cord and Hudson, "Some trends in UT")

Smith's paper in the Proceedings in May 1972, seems to provide a fairly definitive history (page 481) citing the CCIR Study Group 7 Interim meeting in 1962 and CCIR Xth Plenary Assembly in 1963 (Vol III, p193), as well as an earlier recommendation of the IAU XIth General Assembly in 1961 ("Resolutions adopted by comm. 31" Trans IAU, Vol XI B(1961), p 329)

>
> Familiar with any service acronyms like BFD?

Sure.. but this is really a Tiny FD..

But, I really would like to find a definitive printed reference, as opposed to the recollections of folks present at the birth. Think of it as something akin to the citations in the OED. Once you have that golden reference, discussions like this one end in a hurry.

It's also because I'm casually interested in the obscure history of things like this. A co-worker asked the other day, "Why is wine in 750ml bottles, and when did it change from whatever they used before the metric system existed?"... turns out it's actually a fairly recent change. Another interesting discussion had to do with the use of "transfer standards" when building the pyramids in Egypt: failure to calibrate your working cubit against the standard within the calibration interval was punishable by death. No "For indication only, out of cal" stickers there, apparently. {I'm also looking for a definitive source for that story...presumably it would be in hieroglypics.. as one can imagine, though, there's a lot of very odd stuff out there when you bring up anything ancient Egypt related)

Exactly! All you are doing is providing a low impedance
to ground so the return current gets back to transmitter ground
instead of the travelling up the outside of the coax.
Myths are really hard to put down

I guess I should have called it a transformer. Although, it could be a
balun, like they use on output stages of RF amplifiers; 5.6 Ohm balanced to
50 Ohm unbalanced.

Ed,

The way in which you dealt with the transition from the open wire
feedline to the SGC237 unbalanced tuner is relevant. As is whether or not
you bonded the tuner 'ground' terminal to the roof.

Your description is short on relevant detail.

Owen

I know they are all transformers I was just wondering if there was a
specific name for a balanced to balanced transformer. I have just never
heard the term. I propably shouldnt make post in the wee hours of the
morning while under the influence of Flexeril and oxycodone either.

2397. Ferrite Chokes: What is the maximum impedance that can be obtained?

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-16 21:02:21 UTC
From: Mark <makolber@yahoo.com>
Message-ID: <1192568541.078033.195780@i38g2000prf.googlegroups.com>
Source record: 35429

The best way to ask my question is to use a thought experiment.

Imagine I have a bucket of ferrite rings. Assume that the permeability and other material properties of each ring is such that I get about 100 Ohms of resistive loss for one turn through a ring at 144 MHz.

Now assume I have 19" whip on top of a car connected to a 144 MHz transmitter. If I slip one ring over the whip and let it down to the bottom feedpoint, it will attenuate the signal by adding 100 Ohms in series with the feed of the antenna which otherwise would look like about 30 Ohms. That seems clear and seems to agree with common sense and observations.

Now if I stack up 20 ferrite rings on the antenna, if we analyze each ring as a lumped element we would have 2000 Ohms in series and essentially an open circuit and little current or power will flow.

However this does not pass the common sense test. Common sense says the ferrite tube will absorb the energy from the antenna and potentially will get hot and that the feedpoint Z of the antenna will NOT raise indefinitely with more and more ferrites but rather it seems it would level out to some value. We need to use distributed rather than lumped analysis.

Bottom line question... How to determine the feedpoint Z of a wire that is inside a ferrite tube?

thanks
Mark

Sounds like a really neat setup... on the other hand, it may be a
bit much for my poor MAC-II clock. <Grin!>

Um. I just noticed.

Yesterday I powered the clock off and added a "line out" jack so I
could record the received audio. I got distracted here and there,
and when I put it all back together I couldn't get WWV to save my
life. I finally ripped out my wiring, assuming I'd inadvertently run
a wore too close to the RF stuff... but even _that_ didn't help.
I'm now concluding that I reacted too rapidly, that the WWV signal
had simply faded into the background noise.

Seems to be true today as well. I re-added my wiring, and the
signal was unchanged (still rotten: bits and pieces of WWV tones
fading and returning a random-appearing basis). I can now record
long segments of bits of WWV... plus much louder bits of other
shortwave activity and assorted noise sources.

Ah, well. It'll be back some day. <grin!>

> simple amplifier.

Yup.

Heath's algorithm, or at least my interpretation of it based on its
behavior, is to require clear reception -- from start to end -- of
complete TOD "frames", and to only statr the display running when
they're reallyREALLYsure they're locked in.

I have a feeling that one could do a more "statistical" approach and
get better results on poor signals. For example, it appears that
the MAC-II requires that, to be acceptable, a BCD TOD "bit" has to
have its start and end within certain time boundaries. On the other
hand, one could capture whatever bits of 100Hz tone were around and
attempt, over time, to fit them into a pattern and see if it matched
a valid WWV frame. You'd have to take into account that the
contentsof the frame (the TOD) would be changing during your
accumulation, but I think it makes more sense to strip and squeeze
every useful bit of information one can get out of what one _does_
receive rather than waiting for life (or propagation) to be nearly
perfect.

But that's for _next_ month. <grin!>

I noticed. Yesterday all those really clear tones and voice
segments vanished while I wasn't paying attention. I can still hear
enough WWV on occasion to know it's still there, but it's not even
close to being strong enough to start the clock running.

Thanks for the pointer; I didn't knwo that there was a free version
available. I'll check it out when I get a chance

Well, I hope it continued for everyone else, but for me the WWV
signal has faded back into obscurity. I can occasionally hear
small, dim fragments of its former glory, and that for only 10-20
seconds at a time.

I guess I really should have sacrificed that goat. <grin?>

If you take a regular transformer and connect it between a "balanced" (symmetrical) system and "unbalanced" (asymmetrical) system, is it a BALUN? Then does it change to an UNUN if both sides are asymmetrical and a BALBAL if both are symmetrical? What does a BALBAL or UNUN do? What does a BALUN do?

> than lumped analysis.

Yes. The effect of a ferrite ring part way up the antenna won't be the same as one at the base. A 100 ohm resistor in the center of the vertical will add 50 ohms at the feedpoint. One 3/4 of the way to the top will add about 17.5 ohms.

Regarding the ferrite absorbing energy from the antenna -- the amount absorbed will be maximum when the ferrite's impedance is the complex conjugate of the antenna's. For example, if the vertical is resonant and grounded with no feed system, you'll get maximum ferrite heating when the ferrite's impedance is around 36 + j0 ohms. If you add more ferrite, the amount of power absorbed from a passing wave and delivered to the ferrite will decrease, approaching zero as the ferrite impedance increases to a large value.

> Bottom line question... How to determine the feedpoint Z of a wire
> that is inside a ferrite tube?

You could probably do a pretty decent job with an antenna modeling program, placing a number of lumped loads along the wire.

I'm puzzling over this, Roy. It seems like this assumes some source impedance driving the antenna, but maybe I'm missing something in your analysis.

My thought-process is to treat the antenna as an impedance Z1, the ferrite an impedance Z2, and the source an impedance Z3, the three of them being in series. I suppose thinking of the antenna as a constant impedance as you change its environment with ferrite might not be quite right, but to the degree that approximation is correct, then I'd expect maximum ferrite dissipation (absorption) would occur when its impedance, Z2 is equal to the complex conjugate of (Z1+Z3). On the other hand, if I feed the antenna with a constant current source, the ferrite dissipation increases indefinitely as the resistive component of its impedance increases.

Am I missing something?

Cheers,
Tom

Radar antennas ar also checked in this manner. Data about where the sun will rise on the horizon is known so it is realativly easy to determine how accurate the radar's azimuth alignment. This used to be a real pain requiring a facility shutdown to acomplish the task. Now there is a PC based device that connects to the Azimuth Change Pulse, Azimuth Reference Pulse, and video ouputs. Not only is the boresight azimuth of the antenna verified but also the shape of the pattern with the radar online. Data recorded is also used to verify positioning of permanent echos. The device works on both 2D and 3D radars.

SG237 tuner is not "bonded" to the roof ground, SGC does not suggest doing such a thing, and in this case, it would not be possible anyway since the "ground" side of the tuner is also one side of the balanced antenna feedpoint. The SG237 is feeding about 14' of 600 ohm open ladder line, spaced about 1 foot off the aluminum mast, up to the feedpoint of the antenna, a 75M dipole (61' per leg). The tuner is sitting in a plastic box, about 1 foot off the roof.

Whether a transformer works balanced to balanced, unbalanced to unbalanced
or balanced to unbalanced is determined by ground reference. The transformer
just steps up/steps down voltage and current just like a power supply
transformer. Like it doesnt matter whether a power supply transformer is
connect to a balanced main or one side is grounded or whether the output has
a grounded side or not neither does it matter to an RF transformer.

Jimmie

2412. Re: Ferrite Chokes: What is the maximum impedance that can be obtained?

Source record: 35344

Thanks for the comments. Once again, I scanned a posting too hastily, and somehow missed the "transmitter" part. My comments were appropriate for a receiving antenna, not transmitting. So let me try to answer both Tom's and Mark's postings more appropriately.

None of us has a constant current source with which to drive an antenna, but generally a source with a fixed amount of power and a finite source impedance. If we did have a constant current source, then yes, adding more and more ferrite cores would result in more and more power being delivered by the source, a larger and larger fraction of which would be dissipated in the ferrite. A 1 megohm resistor would get a bundle of power from our source, and a 10 megohm resistor would get 10 times as much.

If we have a tuner, we can adjust our source impedance over some range. Provided that the feedpoint impedance is within that range with the ferrites in place, we can deliver all our power to the ferrite-antenna combination. I believe that the fraction of the power applied to the antenna which ends up in the ferrites monotonically increases as we add ferrites (assuming we don't move the previously added ones). If the ferrites were all at the base, the equivalent load circuit would be just two impedances in series -- the ferrite impedance and the antenna feedpoint impedance, and it would behave as Tom said. But putting the ferrite cores anywhere but the base changes the antenna current distribution, which has a potentially complex effect on the feedpoint impedance other than just adding the transformed impedance of the core. This means that not only does Tom's Z3 increase as we add ferrites, but Z1 changes also.

If I had a huge metal roof like that, I would be tempted to try one of the shortened verticals. The kind that requires radials - which would be your roof.

You are running coax from the tuner to the shack, right; with just the 14 feet of ladder line?

One of the things I learned while having to set up an antenna using an auto tuner is that they seem to work best on random lengths of wire. I define random length as any length that is not close to being resonat on any frequency you will ever be using. After expeimenting with several tuned dipoles we gave up and used a 33ft fiberglass vertical whip that tuned well on all bands. I would like to hear whether or not others have had similar experiences.

The feedline is doing more than transporting energy to the dipole centre,
it almost certainly carries a significant common mode current and in that
case is just as much a part of the radiating system as the dipole itself.

So, isn't the coax and control line to the SG237 carrying current mode RF
current, ie contibuting to radiation.

Inch by inch, the detail unfolds.

Ed, sounds like your radios are into VSWR turndown from the inability of the tuner to match at the low end. It could be that the Z at 3825 is going high which a lot of tuners can't handle--or could be very low, same problem, no match. Try adding some more length to the dipole if you can and see if it tunes better at the low end. Even if you only drape pieces down at the ends would help if you can't extend more horizontally.

Hi Dale,

Interesting.

I should have noted in the article that Rex's measurements were made with an ordinary SSB transceiver (behind a transverter), the same receiver that is used for normal QSOs.

In power engineering, the Greek letter, Theta,
is usually used to denote the phase angle between
the voltage and the current. V*I*cos(theta) are
the watts, i.e. real power. V*I*sin(theta) are
the vars, i.e. reactive volt-amps.

2426. Help identify 3 ele beam

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-17 13:45:19 UTC
From: radiomuseum@msn.com
Message-ID: <5543-471611EF-3635@baytvnwsxa002.msntv.msn.com>
Source record: 35358

I bought a 3 element trap yagi antenna that was disassembled. I was told it was a Hy-Gain model. After laying out the parts I can see that it doesn't look like a Hy-Gain model because of the following:

1. It uses large diameter, single traps. These are identified with color coded lables (red, green and blue - radiator, director, etc.)

2. It doesn't have a "beta-match" - rather, it looks like the driven element is directly connected to the coax. The mounting of the driven element is almost exactly like the Hy-Gain style with insulators that are mounted into a clamp that surrounds the boom.

3. The director and reflector use boom mounts that are different than Hy-Gains. The mounts are made from aluminum extrusion and use a circular opening to mount to the boom and have a wide, flat top that the element bolts to.

Does anyone know what make and model this 3 element beam is? After I 'ID' it I can then get the assembly instructions so I know what dimensions to set up since all of the joints on the elements are "sliding joints" with clamps,

Thanks for the help,
Henry W7YBS

This is exactly like my old Mosley TA33Jr. Not at all like the HyGain TH3.
Ditto for #2. On my TH33Jr, the elements were mounted via aluminum blocks
with little U bolts. If it is Mosley, the length of the boom will be a
giveaway as to which model. I would try to download some manuals from the
Mosley web site; it might be mosleyelec.com.

I will answer my own question...

In the absence of an effective device to prevent common mode feedline
current, your configuration where one side of the ladder line connects to
the 'ground' side of the nominally unbalanced tuner, and that same tuner
terminal connects to the outside of the feedline coax and control wires
(at RF), then you have a continuous RF common mode path to wherever the
coax and control lines connect and so on, they are just as much a part of
your radiator as the dipole wire.

Analysis of the 122' entre fed wire in isolation of the rest of the
antenna system are inadequate in explaining the difficulties you
encounter.

Owen

Henry:
What you have is an old Wilson antenna, most likely a System 33.
There are some manuals on the web, but I don't remember if this would be
one of them.
Majestic Communications here in Memphis bought the Wilson line many years
ago.
They have a FEW parts left, but they should be of some help for a manual.
Try 901 / 794-9494, and don't let them know I sent you!!!

Unless Mosley has changed their policy they do not have any manuals on their
web site. A local ham tried to get some emailed from them and they would
not do it, but would sell him the manuals.

> 14 feet of ladder line?

Yes, 14' ladderline from tuner to antenna center. About 100 ' of
RG-213 on roof and another 30' or so going down to station inside
building. We have a coax choke balun located in line on the roof about
8' before the coax goes down in the building.

Not sure what SGC recommends regarding balanced antennas.... will review their info. However, I have read numerous reports from hams who have used SGC and other similar tuners to feed balanced lines. The only important condition was to use a choke balun to keep RF from coming back down the coax shield.

Yeah, inch by inch. I hate to fill up the post with too many details as some people grab something insignifcant and go off on a tangent.... however, the devil may be in the details.....

You're right on the current in the shield. We have a choke balun, currently located 85' down the coax toward the transmitter. I have it scheduled, when it stops raining, to move it up to the input of the SG-237 coupler unit. The Choke balun is homemade, 6" diamter, about 11 turns of RG-8X coax. Does that sound sufficient? I didn't make it or provide it. There is no control line for the SGC coupler unit. It only requires 12VDC @ 300ma and we are providing that by using a couple MFJ DC adapter units to feed the 12VDC up the coax.

You need to visualise that you what you have looks like a dipole with a
wire from one side of the centre following the path of the feedlines to
the choke and from the choke on to wherever.

The choke balun introduces a common mode impedance in that equivalent
wire, but it does not necessarily eliminate common mode current, rather
it modifies the amplitude and distribution of the common mode current.

I especially liked the experts who wouldn't use a B&W antenna under
any circumstance because it was inefficient. Even when the uses
included ALE, frequent frequency changes, and use in hostile
environments. They just gotta squeeze every last db out of a piece of
wire.

My SG-230 manual says NOT to connect any transmission
line to the tuner output - to connect only an antenna.

Richard, I don't think this one is. Its just a "barrel" type device
located in the coax run to the SGC coupler, about 1 foot from the input
to the SGC coupler.. There are no other connections or long runs of
anything going away from the coupler or the antenna. The MFJ adapter
merely filters the 12VDC off the coax center conductor and routes it
through a wire a couple feet long into the coupler 12VDC input.

SGC manual for the SG-237 says it is recommended to mount the coupler at the antenna feedpoint, but it will work on anything, including balanced line. They show a similar example to what we are doing in the manual.

Antenna systems are often a lot easier to analyze and understand if you put aside concepts like "counterpoise" and "ground".

An antenna is a two terminal device, even if it's "end fed". The transmitter is also a two terminal device. Connect the two together and you have an electrical circuit. Like any circuit, the current leaving one terminal has to equal the current going into the other terminal.

So what happens with an end fed antenna? Well, whatever the current going into the antenna (and current must go into it, since the power into it is I^2 * R, where R is the sum of radiation and loss resistance), an equal and opposite current must go somewhere else. If you succeed in completely choking off the current going somewhere else, you've also succeeded in choking off the current going to the antenna. So you don't want to do that.

Conductors don't care what label you put on them -- calling one a "ground" or "counterpoise" doesn't give it magical properties. When a current flows on a conductor, it creates a field. This field will radiate unless canceled by other fields. So the "somewhere else" that the current flows is just as much an antenna as the supposed antenna is.

If the current has nowhere else to go, it'll go down the outside of the coax, which will effectively become the other half of a dipole. If you choke off the current on the outside of the coax, it'll go somewhere else if it can. But if there is no other place, then the current to the antenna will drop -- the feedpoint impedance will increase.

If the current goes into two or more radial wires which are symmetrically placed, the fields from the wires will largely (but not completely) cancel, so the net radiation from the radials will be small. This can reasonably called a "counterpoise" -- a place for the current to flow without creating much radiation. Or you can connect the antenna to a buried radial field ("ground"), which behaves much the same way, but with even better field cancellation. But people often put these names on other configurations, expecting the currents or fields to behave differently than on other conductors.

But the things to remember are that all antennas have two terminals, and the current into one equals the current out of the other. And current

flowing along any conductor creates a field, whether you consider it to be an "antenna" or not. Keeping this in mind helps a lot in understanding end fed and other antennas.

Minimal training? Just because they're not making ditty-boppers any
more doesn't mean they are minimally trained.

The gov't uses these a lot for network communication where operation
includes ALE, frequent frequency changes, and use in environments
where adjusting antenna length several times a day may expose soldiers
and airmen to hostile fire.

Perhaps the SG-237 has some protection that the SG-230
didn't have? The wording in the SG-230 manual suggests
that, since the autotuner is capable of developing
voltages high enough to cause open-circuited coax
to arc, discretion is advised.

You might not need that tree,but instead stiffen the 2 TV masts,by
fitting (in the middle of each mast) 2 outriggers perpendicular to the
mast in the same vertical plane in line with the antenna.
You then connect the free ends of the outriggers with both top and
bottom of the mast using steel wire + tensioners.

Interesting aproach as to what a good engineer is.
It goes without saying that the application has to be considered, even
Yogi Bear
would have come up with a better one than that and he is not an
engineer.
As an engineer myself I consider a engineer or "expert" is one that
will consider
anything unless science has definitely ruled it out and that doesn't
neccesarily
include what has been written before the question arises. Natuarally
that means
not ruling out trying ANYTHING unless one considers their minds
developed enough
that it is satisfactory to go thru the thought processes only.
On that basis this newsgroup is full of fake " experts"!

Tam,

Wouldln't that would be a very bad idea, at least in our particular case? As I pointed out in the start of this thread, we are feeding the antenna with about 14' of 600 ohm ladder line from the output of the SGC antenna coupler. Isn't a choke balan used to prevent the flow of current in the outer braid of a coax feedline? We certainly wouldn't want to be choking any RF coming out of the SGC coupler going to the antenna!

Ed

Tam,

Can you explain the difference between putting the choke adjacent to and
on either side of the tuner?

Actually John my beef is that the rule for the most efficient
radiation
is that "if a radiating element is resonant and in equilibrium it can
be of any shape, size or
elevation". Yet that is ignored by the so called experts of the
amateur ranks.
I can only assume that most think themselves as being experts that
they do
not find a need to get up from the couch and try things knowing that
there
is no room for surprises over their own superior brain power.
How many would admit that :for a given polarization the best results
are NOT
at right angles or parallel to earth" ? And as somebody said "If it
was really
true it would have been invented a long time ago" as if all
discoveries have
their own time scale for discovery and time has expired for antennas

Hmmm, take the cover off any HF tube transmitter. It has an element that is resonant - called the Plate Load. It is of any shape. It must be quiting Librium. It is of any size. It is at some elevation (you may raise the transmitter if you wish).

Yet and all, it makes one of the worst HF antennas ever to come down the pike in the past three centuries or two millenniums.

We can all agree that if Arthur had any pride in his theory, he wouldn't be building antennas having already satisfied EVERY proviso with a Plate Load.

>Yet that is ignored by the so called experts of the
>amateur ranks.

EVERY amateur can test this one idea. Most who did, abandoned this theory immediately as obviously deeply inferior.

No experts were called, implicated, consulted, used or maimed in the making of this announcement - except, possibly, the previous two correspondents. Torts limitations have capped their flamboyant claims to the value of their posts: 2ï¿½ (adjusted for inflation equal only to the Weimar Republic Mark).

You make my point. I have a lot of pride in my findings and
as yet no amateur has made it otherwise they would be shouting
from the roof tops. There are many so called experts who write
about antennas, some even have written books no less but they
get so upset when others write things down for antennas I
suppose because they have gone thru life without making one experiment
relying on their superior brain power so they do not have to lift a
finger.
If they choose not to agree then all others are frauds no less.
Kudos to JS he actually made a Vincent antenna for himself to prove
things.
Kudo's to those who have AO optimisers where they can model these
things for themselves.
Yes a optimizer bound by Maxwell's rules produces the Gaussian
radiators if you ask for
arrays, a radiator or maximum polarity radiation and without tieing it
down to a planar form.
And yes, all other antenna programs verify what the AO optimiser
program supplies.
I don't give one hoot for what you think about it since you do not
posses
an engineering degree and never writes anything of substance, where as
this discovery is all mine.
Oh and another thing I suspect Roys program would also verify the
results of the AO
optimizer just by duplicating the results given since he doesn't
posses any optimiser features.
Are we ready to say that if a antenna program based on Maxwell's rules

provides a gaussian antenna
then programs based on Maxwell follow the "garbage in garbage out
adage". Your choice
It is unusual for me to correspond to you because of your endless
lies and mockery of other people so make the best of this one as
it is going to be a long time.....

thanks for the replies...
so for talking purposes:

Z1 is the antenna feedpoint Z and we will define "antenna" as the
exposed wire after the end of the ferrite tube.

Z2 is the Z of the wire passing though the ferrite

Z3 is the source Z which I will stipulate is 50 Ohms

OK as we add ferrite to the antenna, Z1 changes because the antenna is
getting shorter as the ferrite is getting longer. i.e. if there is 7"
of ferrite, then there is only 12" of exposed antenna and it is

elevated over the ground plane so Z1 is going up. In the end case, when the ferrite is 19" there is no antenna Z1 becomes infinity.

Then looking into the base (thinking as lumped elements), we have Z2 + Z1. Since Z1 is infinity, the base must look like infinity, but this does not pass common sense.

In other words, what is the Z looking into a 19" wire that is inside 19" of ferrite. Thinking in lumped element terms, it would be very high and little power will flow. Thinking in distributed terms there will be some relatively low Z looking into the base, power will flow and the ferrite will dissipate heat. The base Z would be related to some property of the ferrite like the property of free space has a Z of 377.

What is that propery and what would a typical Z be?

Mark

So, art, you are quoting yourself as an authority, whose beliefs are ignored by others having academic credentials/experience in the field of professional antenna engineering -- in which you have admitted you have NO credentials?

> How many would admit that :for a given polarization the best results
> are NOT at right angles or parallel to earth" ? And as somebody said
> "If it was really true it would have been invented a long time ago"

Which somebody are you quoting? I suspect you are referring to me in one of my direct email responses to you, which I paste below (my text only). Note that your "quote" above is a great stretch from what I wrote in that email.

\\ Enthusiasm is always good, but if it was possible to do what you outline using the radiation possible on 160 m solely from a structure in the shape of a 4 ft cube, IMO it would have been done long ago.

Some very experienced antenna engineers including George Brown of RCA, Carl E. Smith, John Kraus, C. Balanis and many others have investigated this subject over the last 60-70 years, and have concluded that nothing smaller is as effective on MW as a linear, vertical monopole at least 1/4-wave high, using a good r-f ground.

I'd suggest that you conduct very good pattern and gain tests for whatever you build. This is not a simple project. If you decide to proceed I suggest that your tests be done and documented very carefully with calibrated instruments, and in an acceptable, scientific manner that can be endorsed and repeated by qualified investigators.

If you do that, history suggests that you will find that the performance of your design does not meet your expectations. But better to know that early on, so that you won't publish information that discredits you. //

Ferrites are notoriously non-linear, and thinking of them in
linear terms is liable to lead to disappointment. Look at
the manufacturer's data before you come to any conclusions regarding
how any of them behave.

In reading up on the new rules for patent continuations and cost
changes e.t.c.
I decided to review patents applied lately for antennas.
To my surprise I could not find any new listing of a patent request on
antennas from private entities.
Applications listed were only those that had transferred direct
authority in dealing with the patent office
Now I know personally that there are patents applied for by the
inventors themselves so why are they kept secret
from the public at large? I am guessing but I can only assume that a
private claim can obtain authority
to change content later with the examiners assistance where-as others
cannot. If so this can affect the new continuance rulings immensly.
Vincent got his antenna continuance claims in just about a month
before the rules changed. Rules have also been revised on the
substance of claims presumably to retard the increasing number of
counter claims tho no doubt it will open more paths to circumvent
existing patents. Just like politics, the more you revise policy the
more you increase loopholes and the more money exchanges hands between
those who introduce "corrective" additions. Some fees have gone up by
3% which is rare considering present social security increases so the
PTO at Crystal City is being really genourous

Good advice. In antenna applications, we need to strive to keep the flux density low enough that ferrites behave essentially linearly. If we don't, harmonic generation will result.

Fortunately for us, the flux density decreases as frequency increases, all else being equal. Also, many ferrites which are commonly used for common mode chokes (current baluns), EMI filters, and the like will get hot enough to explode before the flux density gets anywhere near saturation.

Maybe because it's not true.. :/
Whether or not an antenna is resonant means very little.
Most any wire will radiate nearly all power applied to it.
It doesn't matter if it's a full wave, half wave, quarter wave,
or even 1/16 of a wave.
And I don't even consider myself an expert, and can
comprehend and retain that simple fact of life.
My usual antennas used do happen to be resonant, but it has
nothing to do with the efficiency of the antennas themselves.
The reason I radiate over 90-95 percent of my power is because
I'm feeding the 50 ohm antenna with fairly low loss 50 ohm
feed line from a 50 ohm radio with no garbage in between.
In other words, I'm getting most of my power to the antenna.
And like I say, once you get it there, it will be radiated, no
matter what size or shape the antenna.
It doesn't take an expert to know that. It's in most all of the
books and can be read by anyone.

Would I use an antenna with an intentional resister?
No.
Do I care if anyone else does?
No.
I have ways of doing the same "all band" job and not lose
efficiency. You will never see me running a dummy load
on a stick or wire...
But thats just me.. I'm kind of anal when it comes to turning
my RF into heat.

The choke suppresses the common mode signal. There will still be current flowing on the shield which will have the same magnitude as the current flowing in the center conductor. You are not throwing away any energy by doing this. If you put the choke at the antenna feed point, the transmission line will not radiate and act as part of the antenna. The choke as you described it could also be called a 1:1 current balun. You might want to take a look at the ARRL Handbook.

As for the 600 Ohm line, it is not obvious that 14 feet of 600 Ohm line with an SWR of 120:1 is better than 14 feet of RG8 with an SWR of 10:1. (I came up with an impedance at 3800 of 5 Ohms, assuming a perfect ground. If the roof is not that good a ground, you will want to add a couple of Ohms to that).

You guys could solve a lot of the mystery by measuring the SWR as close to the feedpoint of the antenna as possible.

Why not? A zero length antenna is an open circuit, which has an infinite impedance. What would you expect the impedance of a zero length antenna to be?

> In other words, what is the Z looking into a 19" wire that is inside

That's correct.

> Thinking in distributed terms there
> will be some relatively low Z looking into the base, power will flow
> and the ferrite will dissipate heat.

Can you explain how you reach that conclusion?

> The base Z would be related to
> some property of the ferrite like the property of free space has a Z
> of 377.

The ferrite with wire inside comprises half of a circuit -- I posted more about this a day or so ago. The only reason current flows into an open-ended wire like a whip antenna -- that is, the only reason the whip

doesn't have an infinite input impedance -- is that the field created by the alternating current in the wire couples to some other conductor which is the other half of the circuit. The field induces a current in that second conductor which flows into the other terminal. And that current creates a field which couples into the whip, sustaining current in it. If you could prevent the field from the wire from coupling to the ground plane, no further current would flow into the wire and it would indeed look like an open circuit. The ferrite does essentially just this.

> What is that propery and what would a typical Z be?

The ferrite has an intrinsic impedance, as does free space and every other medium. It's the ratio of E to H fields of a TEM wave in the material. But what does that have to do with this?

Hi Mark,

Good question, but difficult answer. I think the best way is to see
the construction as a transmission line (as you suggested) . If the
ferrite should have no losses, the inductance/m rises significantly.
The capacitance/m rises also (because of the eps.r of the ferrite
material).

So you will end up with a high Z transmission line with significantly
lower propagation speed. A difficulty is: where is the return
conductor? You can assume the return conductor about 0.125 lambda
away when the influence of the ferrite is not that large. Very close
to the feedpoint, the impedance of the ferrite loaded line is strongly
dependent on the distance from the feedpoint.

When the transmission line would be loss free, the impedance at the feedpoint is strongly dependent on the termination (because all energy may be reflected back). This is in many (wide band) cases undesirable. It is the reason that I do not recommend 4C65 material for current mode baluns at low frequency (the Q of the 4C65 ferrite material is rather high at, for example, 80m).

Sometimes we can be happy that ferrite has (some) losses. In that case the forward and reflected wave both suffer losses and the input impedance becomes less sensitive to load variations at the other side of the one turn ferrite inductor. So practically spoken, yes, when you add infinite ferrites, the impedance will reach a finite value.

In a real world, the situation is more complicated, because when using High permeability cores, you also have high permittivity. The propagation speed in the ferrite material itself can be that low that the flux density distribution is no longer uniform. This causes the effective permeability to change faster then expected based on the datasheet of the ferrite material. Above a certain size, adding thicker ferrites (in outer diameter) does not increase the inductance/ loss.

When you would take a long thick ferrite tube, the field will even not come out of the ferrite because of the attenuation in combination with the low EM wave propagation speed inside the ferrite. Ferrite absorbing tiles also make use of both the epsilon.r and permeability.

So finally I did not answer your question about how to determine the feedpoint impedance. Probably you will need full 3D EM software that can handle 3D structures of different mu and eps. As far as I know, all momentum based EM software cannot handle this.

Hope this will help a bit.

This might just be really loose language, but assuming fully effective skin effect (which is a reasonable assumption for most practical coaxial cables at HF):

The current flowing on the outside of the inner conductor is accompanied by a current equal in magnitude and opposite in direction flowing on the inside of the outer conductor.

Skin effect isolates the inner of the outer conductor from the outer of the outer conductor, but current on the inner of the outer conductor may contribute to current on the outer of the outer conductor depending on the treatment of the shield at the ends of the cable.

So, a choke formed by coiling the coaxial cable or placing ferrite sleeves on the cable affects the impedance in the current path of the outer of the outer conductor and does not directly affect what is happening inside the coax.

Mind you, this concept is not universally accepted by hams.

In the case of coax, so-called common mode current flows only on the outside of the outer conductor, and differential mode current flows only on the inside of the outer conductor and outside of the inner conductor.

The second conductor of the transmission line is the ground plane.

I don't believe that's necessary. As you say, the field doesn't escape the ferrite. This means that the E field between transmission line conductors (the whip and ground plane) is zero. Therefore, the impedance of the line (E/H) is infinite. The loss of the ferrite is adequate to suppress any reflections from the end of the line. A reflectionless, infinite impedance line will have an infinite input impedance. This is, as it should be, the same result I got from a somewhat different perspective.

So a electrical generater doesn't keep turning in one direction
but instead it occillates at the desired frequency.
I have never seen one do that!
And "end effect" is the confusion created at the top of the radiator

The fundamentals of EM radiation are defined by natural laws, which even 50 years ago were rather well understood.

New antenna designs always will be possible, but all of them of necessity must be based on, and follow natural law.

'end effect' is an effect of the capacitance seen from the end of the
antenna to ground or the other part of a dipole.

how does a generator come into this? you feed current into a wire with an
open end, it gets to the end, reverses direction and goes back to where it
started. no frequency was stated or implied all you asked was where there
'current' went... that could be any kind of current including a step or
pulse or sinusoids of any frequency.

John

This antenna is best used for receiving. While it could be used for transmitting, the losses through the matching and switching networks mean that other designs are more efficient at radiating a signal.

For example, ferrite rods make great compact receiving antennas, but are practically useless for transmitting. Just because you have a great receiving antenna, it doesn't mean that it will transmit equally well.

The current comes from a generator does it not? So how is that current
produced?
I see a generator turning in one direction only all the time where you
are suggesting that it is occillating.

Pretty hard to draw a circuit if it tracks back the way it came.
Draw a graph of an occillating current as you would see on a scope
that shows two degrees of freedom.
Does the "x" direction stop after a half cycle?

I don't have to be an engineer to question this one. An electrical
"generator" does indeed keep turning in a single direction. It has
brushes and split commutator rings to keep the current flowing in only
one direction. That is in the very nature of a "generator." The device
I suspect that you are alluding to is an "alternator" in which a
magnetic field is rotated through a coil of wire and passes through both
halves of the coil at the same time. Since in a well designed, single
phase alternator the center of the magnetic field and the center of the
coil of wire are coincident the current does indeed alternate because
unlike a generator the alternator does not include any means of flopping
the connections on the coil in time with the magnetic field. So as the
negative and positive fields of the magnet pass through each half of the
coil of wire in turn the current reverses direction.

When the signal arrives at the open circuit end of the antenna, current can not continue its forward flow. It abruptly stops, no longer producing a magnetic field.

Energy from the magnetic field is converted to energy in the electric field for an instant (Cecil`s famous conservation of energy). This produces an insreased voltage at the open circuit end. This incresed voltage has more capacitive effect, akin to the "Miller effect" caused by the higher signal voltage on the plate of an amplifier vacuum tube than on its grid.

On a transmission line or on an antenna system, we used to call this capacitive action the "Ferranti effect"

Thanks, Richard. I notice that article references King, I assume
Ronold W. P. King, who wrote some very nice qualitative explanations
of various linear and loop antennas in King, Mimno and Wing's
"Transmission Lines, Antennas and Waveguides."

There's also a nice explanation that I feel is quite accurate in
Joseph Boyer's "The Antenna--Transmission Line Analog," from Ham Radio
magazine, April and May 1977. I believe I have it somewhere as a PDF,
scanned from the article.

Cheers,
Tom

All this is faulty logic manufactured to suit your intelligence.
Radiation is a function of the release of energy from capacitance and
inductance
during a cycle i.e. a parallel circuit called a "tank circuit: which
can also
be seen as a loss less system ala a pendulum.
This goes back to what I say about books. Anybody can write one. It is
up
to the reader to follow the dots of logic displayed to determine
agreement
not to swallow it and memorise it.

"Who says so?"

Many. It is commonly held opinion.

Frederick Emmons Terman writes on page 89 of his 1955 opus:

"When the load impedance is infinite, Eq. (4-14) shows that that the coeficient of reflection will be 1 on an angle of 0. Under these conditions the incident and reflected waves will have equal magnitudes at the load, and the reflection will be such that the voltages of the incident and reflected waves have the same phase. As a result, the voltages of the two waves add mathematically so that at the load E1=E2+EL/2.

Best regards, Richard Harrison, KB5WZI

No.

You probably mean "regressive" winding, where you wind half the turns, cross the wire to the other side of the core, and wind the remaining turns in the other direction (but the same sense) around the core. If you wind half the turns in each sense (half where you pass the wire downward through the center of the core each turn and half where you pass it upward), you'll end up with nearly zero impedance and a very poor balun.

The advantage of the "regressive" winding technique is that it reduces the end-to-end capacitance of the winding. I've found that with high Q inductors (but ones operating well below self resonance) it typically improves the Q by around 10 - 15% or so, which is usually not worth the trouble. With the sorts of ferrites commonly used for baluns, Q is typically one or less over the operating frequency range, so "regressive" winding makes no difference at all. In any case, it makes no difference in core flux density.

>Applications listed were only those that had transferred direct
>authority in dealing with the patent office

All the transfer of direct authority means is that the inventor has hired an attorney. The fact that an individual hires a patent attorney to help them prepare the application doesn't mean they are not an individual inventor working by themselves out of their basement. Its just that the USPTO web page does not have a separate search criteria for applications where the inventor is acting "pro se", that is, without the help of an attorney.

>Now I know personally that there are patents applied for by the
>inventors themselves so why are they kept secret
>from the public at large?

All patent applications are published 18 months after their filing date. This rule was enacted about ten years ago to comply with the provisions of the GATT treaty, whch simply made USA practice compatible with what the rest of the world had been doing for decades.

I am guessing but I can only assume that a
>private claim can obtain authority
>to change content later with the examiners assistance where-as others
>cannot.

If you look at the USPTO web page under the "Public Pair" heading (its under the general "Patents" subcategory), you can view the actual file contents of every application 18 months after filing. This includes the original application and claims as filed -- not just the content, but a scan of the actual document that was filed.

If so this can affect the new continuance rulings immensly.

The problem with the old continuation rules was that there was no penalty for filing infinte continuation applications. Now if you file a third one you have to convince the USPTO that it is appropriate. I suspect that the new rules will be successful in discouraging excessive continuation filings.

>Vincent got his antenna continuance claims in just about a month
>before the rules changed. Rules have also been revised on the

Its not a cost of living raise -- its based on the previous year's
actual expenditures. Some years the fees actually go down.

Right, it is opinion not factual.
There is no proof what so ever that is what happens.
So you must also consider alernatives.
Current can go out into space which doesn't seem plausible
Current can flow inside the copper wire which is plausible

So now we have a measurement problem. How can we track
one path from the other or you come up with a reason
that it can't flow thru the center of copper

>
> Frederick Emmons Terman writes on page 89 of his 1955 opus:
>
> "When the load impedance is infinite,

WELL,WELL,WELL!

Probably true except for one thing.... THE LOAD IMPEDANCE IS NOT
INFINITE !
See what I mean about books. It is not a case of remembering what
somebody
said it is a case of connecting the dots with good logic that one
finds
unmistakable agreement.
Which brings up another point with respect to radiation about which
many admit is not known.
If the laws of Maxwell are in agreement with the extension of Gauss
which many say
of the latter is not correct then logic states we should remove
Maxwell.
Problem is that computor programs based on Maxwell laws also confirm
Gaussian law.
So now YOU connect the dots. Maxwell is correct? Computor programs
based on Maxwell
are correct. Computor programs confirm Gausses law extensions re
adding a time varying field.
Mathematics support Gaussian verification of Gaussion law, so
where is the logic of condemming Gaussian law and yet not condemming
all other laws?

Lesson: Use your own logic before referring what you read to memory
otherwise
you are just a member of the herd without a contribution of your own.
Just follow the arse of who goes before youand ignor the smell
Art

Meaningless jabber since it is based on "infinite impedance" which is
in error.
thus the analysis is in error for the circumstances at hand.

They're there. I found one in the first 3 I looked at.

> Applications listed were only those that had transferred direct
> authority in dealing with the patent office

That's not the case. It's not surprising to me that most of the
applications are on behalf of companies that sell things.

> Now I know personally that there are patents applied for by the

You might need to improve your search techniques.

> from the public at large? I am guessing but I can only assume that a
> private claim can obtain authority
> to change content later with the examiners assistance where-as others
> cannot.

You can change the content, but not the substance of a claim.

> If so this can affect the new continuance rulings immensly.

The new (proposed) rules simply require that an explanation be
provided as to why the ammended information had not been included in
earlier submissions.

> Rules have also been revised on the
> substance of claims presumably to retard the increasing number of
> counter claims tho no doubt it will open more paths to circumvent
> existing patents.

The only change being _proposed_ is one where the initial examination
of the application would be of just the independent claims and any
dependent claims the applicant cites in particular.

Congrats on your upgrade, Art.

Another advantage is that it may be convenient to have the winding end on opposite sides of the core... often the case for fitting a balun to a box with input on one side and output on the other.

i don't need a generator to create a current. hook a battery to a piece of wire, watch the current travel to the end of the wire then reflect back. its easy to do the measurements and they match exactly the theory. i use this all the time, its called a time domain reflectometer. very handy for finding breaks or bad spots in feed lines or Beverage antennas. use one for a while and you will become much more familiar with the true effect of currents on wires and reflections.

The important point here is the examiner has the authority to make
changes to the substance and the claims when asked for assistance
from a private entity during the examination without having to
ask for an extended contunuance (I believe that is how it is)
I have made changes in every area with the consent of the examiner

and his superior. Law demands that they supply assistance to any
private entity

Maybe better understood using visible EM waves.
When the medium's index of refraction changes,
reflections are the result. One can learn a
lot about EM wave reflection by looking in a
mirror. With some of the strange concepts about
EM reflected energy that exist on this newsgroup,
it is a wonder how the promoters of such concepts
can look themselves in the mirror. :-)

Thanks for the replies..

so I think you are saying that the 19" wire inside a 19" tube of
ferrite will present a Hi Z a the base and will therefore consume
little power i.e. it looks like an open circuit...

Does that seem resonable to you? It's the the same result as if the
ferrite were copper. i.e a cavity resonantor. I know the answer is
correct for copper but copper is not lossy.

>From the other perspective, the ferrite is lossy so it will be absorbing energy and dissipating heat and therefore the base must look like SOME impedance that has an R comonent.

So I think the more fundamenal nature of my questoin is about how a wire radiates in concert with the return current to the ground plane. What if the wire is surrounded by a lossy medium such that the field is greatly attenuated before it can get to the ground. How does the return current flow and how does energy get absorbed by the lossy medium?

Mark

The problem I have is that a patent request was submitted
as most people know, on the Gaussian antennas. Now with my
present experiments comming to and end(I have a directional
circularly polarised antenna for 160 M which is wound on
2 foot diameter with a lesser dimensional width which is probably
a first, plus I have it placed inside a capacitive field)
there are more additions to be made. Maybe instead of filing a
fresh patent it would have been cheaper to ask for a continuance
on the first request, a rule that I was unaware of. Still once the
money
fees have been payed it probably would be to difficult to reverse
payment
and try for a continuance. Maybe it is best to let a sleeping dog to
lie.

Probably true. I wonder if they would continue
to argue if the 1/4 wave antenna was tubular or is
there another reason that the center of a radiator
is off limits to current flow.
Still you can't blame them if all they know comes
from the ARRL books. After all it is a hobby and in
the early days many did not have the opportunity
for a college education
Best regards
Art

Hi Richard

where is it shown that Art is not following natural
laws?. He has explained every step along the way
and I see no place where he has strayed from natural law.

John, they haven't changed the basic rules! So a company asks if they
can use this or that
and the FCC comes back with a couldn't care less what they use to meet
the existing rules.
So the company now has the liberty to say it has got permission from
the FCC insinuating
but not stating, that a major advance has been made in the industry
at large.
It would appeared so much different if they asked permission to lock
the doors after work every day
and got the same response but that would not have affected the trade
in shares would it?

John, there is no such thing as a fractal antenna. Antennas can only
function in real space-time. It is a only figment of certain matematicians'
imaginations. Sorry. 73

Keep to the discussion at hand. The route to free space was discarded
but there is another route available which you choose to ignore,
Well not you since you just quote from books without personal
voutching.
So let us say Terman chose to ignore or his secretary screwed up.
Unless ofcourse you have dotted the I's and T,s for yourself
and can personally confirm the corectness of what you have quoted.
So pray tell me, what is the impedance of current flow on the inside
of a tube
or down the center of a solid conductor assuming there is no 10 foot
fence placed at the top end of a fractional wave length antenna.
We will leave the lights on for the current to see the inside of the
tube

2520. Miller effect - was: What is the antenna current path or route

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-20 01:55:20 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <gNWdnVJgku5wwoTanZ2dnUVZ_uevnZ2d@bright.net>
Source record: 35252

Dear Group:

A hot button has been pushed. The Miller effect (not to be overly confused with the Miller theorem) stems from an exhaustive analysis of the amplification vs. frequency of very low mu triode amplifiers (the tubes available at the time). The work was published just after WW-1! It was noted that the effect on frequency response of the capacitance between grid and plate was magnified by the amplification of the stage. Miller's paper showed that the effect of the aforementioned capacitance could be approximated by a capacitor in series with a resistance with the combination placed in shunt with the grid-cathode. Several conditions need to be true that were overlooked by later commentators!

Many years latter, Miller's work became corrupted into Miller's theorem that erroneously contended that the effect of the feedback capacitor was the same as a gain dependent capacitor in shunt with the input and output of the amplifier. Various "proofs" have been published that "prove" Miller's theorem. They remind one of HS proofs involving dividing by zero.

It is true that the frequency effect of capacitance between input and output (note, those are nouns) of an amplifier is detrimentally increased as the gain of the amplifier increases. [as gain goes up - the upper half-power frequency goes down] [note the notion of approximately constant gain-bandwidth product for well behaved amplifiers]
However, the simple modeling indicated by "Miller's theorem" only occasionally estimates the relationship between feedback capacitance and upper half-power frequency. Fortunately, the allege convenience of using Miller's theorem in the slide rule days has now gone away. Today, one may use PSpice (or the like) and receive close estimates of the expected performance of an amplifier.

It is difficult for me to see gain at the end of an antenna's wire. The apparent capacitance that exists at the end of an antenna's wire simply exists and is not magnified by anything.

This is only for "published" patent numbers, when you first
apply you are given a reference number only so future
records are kept in one place until a patent number is assigned.
Actually they are behind in their work having only one years data
that you can refer to. I do know that a private company
publishes patent headings only and are up to date within a month
and from what I see all applications list an agent.
How they get this information I do not know.

Sorry.
There is a patent issued and many, many, more in the pipeline.
Look up Fractus antennas or subscribe to the quarterly industrial
magazine
called Antennas.The Fractus company was featured at the Antenna
exhibition in
Denver last month. Entrance fee was about $1000
At the companies inception it won seed money from the military
to continue their work so the antenna is viable.

The chances of them being wrong is about .01 %...
They have only had 70 years to double check themselves.. :/
The size of the small 4 ft antenna is the least of your problems.
Wait until you try to get all your power to it...
Myself, I think this "new" antenna is nothing new at all.
He's not doing anything that hasn't been done before.
But even that point is fairly moot..
The design is an inferior one when it comes down to it.
For a given height of vertical radiator, there is no form of
loading that will beat capacitive hat top loading using
no inductor at all.
Not in efficiency, and not in current distribution.
And even if a coil is needed to tune, it's still the best,
vs other methods. The top of the radiator is the best
place to add capacitance.
Top hat loading gives the most linear current
distribution through a short whip.

So...Do I get to re-invent and patent this new whiz
bang up top loaded vertical...
Har... Give me a break..
Then again, maybe I could talk the military into using
my superior antenna vs his inferior one. I could make
a zillion bucks overnight with all the lucrative contracts.
Move to Beverly Hills... Swimming pools...Britney!

Naw, after mulling it over, I think I'd rather stay in Tejas
with the normal people...

If you go to the hospital to get a bypass, do you want
a doctor that follows proven medical theory and practice,
or do you want Jethro and Granny to have a go at it?
:/

Below from earlier in this thread (quoting Art)...

" I say again, one must have equilibrium for maximum efficiency and
that requires a full wave length radiator and at the same time holding
to the LC ratio for that length. "

Natural law, and decades of field experience with commercial antenna
systems do not support these beliefs.

As others have mentioned, several articles appeared in various magazines about the design of fractal antennas. The basic idea is to fold a standard length of wire using a fractal pattern so that it fits into a smaller space. One solution I saw was to wind a wire back and forth across and along a plank of wood using pins or slots cut in the wood to support the turns. Taking a four inch wide piece of wood around eight feet long and winding equispaced turns you could easily fit 24 feet of wire along the plank.

```
__ __ __
|__| |__| |__| | Using a pattern like this.
```

Other more complex or even three dimensional designs can fit more wire into a given space.

Older interpretations of antenna theory predicted that the interaction between the closely spaced wires would effectively short out the turns and you would end up with the equivalent of an 8 foot length radiating element rather than the 24 feet of wire wound along the plank of wood. While there is interaction, the apparent reduction in radiator element length is not as bad as was predicted. So fractally wound elements can be worth the effort where space is at a premium.

It is significant that the majority of development work into these antennas has taken place for frequencies above 1Ghz. Main applications include mobile phones, RF ID tags, security and remote sensing tags. At Ghz frequencies, exotic patterns can be easily etched onto circuit boards at minimal cost. Koch snowflake like fractal patterns combined with circular whorls seem very popular with commercial manufacturers. A google search will reveal quite a few pictures of what is being produced.

It is not necessary to try and duplicate the complexity of professional designs. The main criteria seems to be to keep the wires as evenly spaced as possible, hence the width of the winding should be approximately equal to the linear step along the plank of wood or whatever support frame you are using, i.e. 4 inches up, 4 inches along, 4 inches down, four inches along, 4

inches up, etc. etc.

As you will doubtless appreciate, this is similar to a three dimensional coil being wound on a former. Because the fractal winding is flat, there are fewer inductance effects.

Obviously fractal antennae are designed for a specific frequency or band, but the type of winding pattern and spacing have an effect on the bandwidth. Obviously you will need two mirror image windings to create a dipole antenna, ideally as closely matched in dimensions as possible. Efficiencies can approach 50% of a full sized radiating element.

Hope this helps

Mike G0ULI

Mac, N8TT wrote:
"It is difficult for me to see gain at the end of sn antenna wire."

Miller effect works in a triode tube by placing a larger signal voltage on the plate than on its grid. This increases the difference in number of electrons between grid and plate.

The charge of a capacitor is the difference in number of electrons on the two plates.

At the open circuit end of a 1/4-wave antenna, the incident and reflected voltages are in-phase and equal in magnitude, thus doubling voltage at the antenna tip. This increased voltage doubles the charge at that point over that produced by the incident voltage alone as Q=CE.

Mac is right. There is no mu factor in an antenna tip but there is a voltage and charge gain.

Best regards, Richard Harrison, KB5WZI

Yes, you to can apply for a patent for yourself regarding an antenna
and for listenning purposes only to boot. But you sir have a problem
or two.
First of all the PTO will not accept anything you "say" verbally which
is
what you are good at. Secondly you have to have faith and
understanding about what you propose. Thirdly you have to put
up front to the PTO and possibly others a substantial amount of money
which instead of pursuing your research you can purchase a
whole new radio set up.
So you do have a choice......put up or shut up
.

Mike,
the definition I arrived at is that as long as the wire represents one
wave length,
is resonant and in equilibrium while at the same time holding to the L/
C ratio of the material in question.
This can be produced with just two degrees of freedom by folding
the wire at the half wave point
and then wind the two wires in pancake shape/form.
You can also wind two in series where capacitive actions
between them can create a variety of results.
The important point is that one must hold to the
conditions set in the definition
(no exceptions)

I feel no great need to re-invent an antenna.
I also feel no great need to bribe the patent office to ensure my
success of this re-invention, or to prove my faith or
understanding in top loaded verticals which were around
before I was born.
I have plenty of radios. Don't really need any more.
I do put up antennas quite often though.
So I guess this means I don't need to shut up.

I agree. Incidently the origin of the idea for fractal antennae apparently arose from the observation that hanging down the ends of a dipole, or bending it to fit a limited site didn't affect the efficiency too much. A university student decided to see just how much bending and could take place before the antenna became unusable and hey presto, the fractal antenna was invented and he had a thesis for his degree.

Yup He is way ahead of the average ham but he did have an engineering
background
now he is making a lot of money with a product that the average hame
decries.
I was looking at Tom's page W8ti and I was very suprised to see that
he states
an antenna must be straight no less plus a lot more in accurate
statements.
He has written articles as have many on this newsgroup but as I have
stated before
believe what you want but often it is not correct.
On this newsgroup I am often reminded of the scene around madame
guillotine with
the . hoards of baying crowds of the ignorant looking for blood.
Have to make a correction on past statements tho, instead of one
wavelength radiator it should read
" one wavelength or longer" because of the genorous number of
harmonics.
Cheers
Art KB9MZ....XG (uk)

Just linear loading with a fancy name..
Or the way I see it anyway..
The thing is... Most consider linear loading as
inferior to high Q coil loading, as long as the
coils are placed at the proper locations to
maximize current distribution.
But I can see their use in small items like
cell phones, etc..
I doubt if I would use one as a ham radio antenna
though.
Heck, my 160m "Z" dipole could be considered a
fractal. Even a dipole qualifies. All symmetrical
antennas can be called "fractals" if you wanted to
be strict about it.

2542. APRSPoint 4.4 is released

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-20 18:54:51 UTC
From: "hxc98@yahoo.com" <hxc98@yahoo.com>
Message-ID: <1192906491.468626.25190@i13g2000prf.googlegroups.com>
Source record: 35273

New in this version,

1. Improved log file replay, with the ability to apply track list and
filters during the file loading process to reproduce different
tracking scenarios, and the ability to adjust replay speed,
2. Added TCP raw data window, and option to turn it on/off for better
performance,
3. Improved subnet filter handling,
4. Streamlined filter, settings, and track options interface, plus
other enhancements,

Visit www.aprspoint.com for more details and download.

2543. "Balancing" versus "cancelling"

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-20 19:34:44 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1192908884.463927.56230@v23g2000prn.googlegroups.com>
Source record: 35274

Looking thru various antenna pages on the web and I continually find reference
to inductance CANCELLING capacitance.
The operative word should be BALANCING and the difference is important . In all cases the capapicitor is still there and operative
as is the inductance.One cannot say they are cancelled so they can be disregarded.
You cannot make either of them inoperative or of no consequence even in the case where a clockwise
wound inductance is in series with a counterclockwise inductance since by definition
both are energy containers. When you have a resistive impedance for a full wavelength without a reactive component per se what it means is that the energy contained in each of the energy containers are equal thus allowing for symetry as in a loss less pendulum. If on does not have a full wave length you can still have equal energy sinks but their release of energy is not synonymous with each other thus there is no symetry.
So concentrate on the word "balance" or "equilibrium" when maximum efficiency is required.
Best regards

Yep, fractal stands for "fractional dimensions". A
dipole is primarily in one dimension. A "ground
plane" is primarily in two dimensions. Anything
that does not occupy all three dimensions equally
qualifies as a fractal.

Sheer insanity and babbly-cockery!

Current "natural laws", and especially as defined by math, allows for a 377 ohm impedance to be given "nothing" (or, the ether--and indeed, there does appear to be some "property" responsible for it--just not the one presently given.)

Allows for a permittivity to be assigned to "nothing", actually the ether.

Allows for a permeability to be assigned to "nothing", actually, again, the ether.

Allows for the spinning of the earth and motion of our solar system to be involved in the equations/math of our antenna/rf calculations.

Nothing should be allowed to be logical, and, therefore, simply "NOTHING!" And, therefore unable to have any qualities, properties, effects, affects, laws, etc.

Until the above is accounted for and sorted into a logical theorem, present "antenna science" looks as if a bunch of African witch doctors are implementing it!

Admittedly, some progress is being made, however, little of that ever sees the light of day here ...

Regards,
JS

I guess I missed the part of Vincent's patent where he invokes modern
cosmological thinking to help explain his antenna.

8-)

Vincent does not claim any radical new physics or math, in the style of EH and CFA. Instead he simply combines several well-known elements into what he claims as a novel device. The USPO allowed his claims of novelty.

You can accept or reject his claim of novelty, but don't try to add some modern mumbo-jumbo more related to pondering the scope of the universe. I doubt that the URI Physics Department would support such ramblings without a lot more internal review.

Before our present physics and sciences stepped forward in an attempt to expand mankinds' knowledge, the same winds blew through the trees, the same sun rose and set, the same rivers flowed, the same earth spun, the same stars were seen, the oceans existed, the same universe lay spread before us--the same, the same, the same ...

However, way back when, spirits and the supernatural where given as explanations, now science attempts to provide the proper explanations--however, "what was" and "still is" was/is seen by all--both those who thought the spiritual/supernatural were responsible--and those who attempted to explain it by "science."

Such is, STILL, as it is today, we are all looking at the same thing, some of these things are, indeed, working--and working quite well--although, explanations may vary as to the "why" and "how"...

No radical changes or discoveries need to be had--just logical explanations had for what already is and has always been ... errors in our present thinking are quite obvious and abundant ... "true" explanations few and far between ...

We just now need to refine our math and knowledge to reflect the true world--accurately ...

No matter what one calls it, equal inductive and capacitive reactance at the input terminals of an antenna system (eg, resonance) is important only in achieving the most efficient power transfer from a source connected to those input terminals having an impedance matching the remaining pure (non-reactive) resistance of the antenna system

==> Antenna system reactance neither absorbs source power nor radiates, whether such reactance is capacitive, inductive, or in "balance / equilibrium." <==

Only pure radiation resistance will do so, and that is set by the natural radiation resistance of the antenna conductor(s), which in turn is related to the mechanical and electrical configuration of the radiating structure, and the operating frequency.

Setting up equal inductive and capacitive reactance values at the antenna system input terminals means that the real radiating structure of the antenna will receive the maximum power possible from a matched transmission line, which will maximize the fields that the system can produce from the net power available from the transmitter.

This general category of antenna is often known as a "meander line", a technique used for making electrically short antennas which has been known and used for a very long time. "Fractal" antennas are a more recent idea. They're a class of meander lines using particular algorithms to do the meandering in a particular irregular way. Among the interesting properties of some of these antennas is the presence of non-harmonically related multiple resonances.

Many claims have been made for "fractal" antennas, among them being that they provide the best efficiency for a given physical area. Steve Best, VE9SRB, has credibly refuted this claim by creating some randomly-meandered designs which are more efficient than claimed best fractal designs. You'll find some of the history of this in the archives of this newsgroup. The EZNEC models he developed are still at http://eznec.com/misc/MI2/ for anyone interested to download and review. Those models were also used for papers he wrote on the topic in IEEE publications and, I believe, QEX. It's not clear what advantages, if any, "fractal" designs would have over random or other meander topologies for amateur use. The allure of "fractal" antennas seems more to be in the interesting mathematics and the cachet of being modern and revolutionary than in any demonstrable performance advantage.

Meander line antennas, including "fractals", share the same properties as other electrically short antennas: narrow bandwidth and high conductor current. The latter can result in poor efficiency due to I^2 * R loss. Meander lines are better than some other methods of loading and worse than others, depending on how the meander and other methods are implemented. It's just one of the techniques which antenna designers have in their bag of techniques to use.

I see your point, but I think the issue you are having with
"balance" vs. "cancel" is more semantics than functional. It is easier
to perceive the issue as a cancellation when making calculations and
design, I think.

don't tell the designers of those funny little cross field antennas that!
their whole theory depends on capacitors creating a ratiating electric field
which then combines with their separately created magnetic field to create
an em wave.

Is this going to be the same garbage that you troted out from
Terman? You still haven't explained why you accepted that there
was high impedance at the top preventing current flow.
The impedance down the center is very low, just the
resistance of the copper or aluminium. When will you be ready to
give the correct interpretation using this new capacitance aproach?
Have we dismissed Miller. Most will agree with the side note you added
regarding what the charge of a capacitor is to which I will
add that there are more Irishmen in London than in Dublin.
Also Scotland has the highest red heds per capitor than anywhere
in the rest of the world but none of these facts have nothing to do
with respect to your wrong readings of Terman. Now you are bringing
forward a new book to take the place of Terman to prove something
that is not relavent to the fact why you posted erronius info.

> frequencies.
> --
> 73, Cecil http://www.w5dxp.com

The capacitor itself does not radiate ie what is
between the two plates but the size of a capacitor does matter when
releasing its charge that creates radiation. Since the time variance
of the charge release is what creats radiation it follows that the
size
of and the constrictions provided make a huge difference. (Read up on
Bernollis
and his work on fluids)
You can have a very small inductance with a very large capacitance
as the L.C. ratio stays intact but the time variance of energy
release
will certainly different in that moment of time when the radiation
pulse occurs
As with standard practices I am not taking into account the
inductance
of the capacitor plates themselves since it just provides an outlet
for posters to avoid repeat of past errors by changing the subject
Best regards

Snip

The non- harmonically related multiple resonance is quite important
now that all ham freqencies are not harmonically related.
I have found that it is possible for a single Gaussian antenna to
be resonant on many frequencies that are not related purely by
balancing the LC ratio at a given radiator length of choice
without reliance on traps or harmonics. These are contained
in there own band pass circuit and which can be moved at will.
The importance being that there is less interference between
band users as well as ambidextry and a constant impedance.
The case for Fractals is somewhat different to ham use in that for an
encapsulated
high frequency SYSTEM it matters not if what some would call the feed
line radiated
since usually power is not a main consideration making it ideal for
stealth purposes
since the fractal meanderings can be made to conform to any shape
structure while
maintaining a desirable LC ratio which with the use of laminated

circuitry is
becoming more available.

Yes that may be true but with the increasing reliance on mathematics
and computors
the gimmicks that come with mathematics are distorting things. Tho an
inductance
may be "cancelled" out it is still there which created a magnetic
field which may
or may not be affected by an alternately counter wound inductance
since energy is still
being used to create a magnetic field amoungst other things. I would
imagine if
the inductances were used for storing energy mathematically that fact

would be
hidden leading research into a incorrect direction.
For me who is working around the LC ratio with respect to antennas
Ithere are advantages
for maximum capacitance and inductance vessels for max time varience
of energy discharge
while at the same time keeping to the required LC ratio at point of
feed since the
larger the storage vessel the faster the energy release or explosion
which then means
a higher velocity for free electrons to carry communication.
Note with respect to the H bomb tests in the Pacific where the more
powerfull explosion
wiped out the Honolulu electrical grid which had not happened before
thus the velocity
of the explosion or release had a direct relationship with radiation.
Best regards
Art

It appears that the above MAY actually be a sentence. However, with
74 words in it, I get completely lost before I get to the end of it.
Would you be so kind as to diagram it for us, Art, or at least divide
it up into something a little more manageable?

Thanks.

Cheers,
Tom

Anyone have any ideas about what one might do with a television receive-only (TVRO) antenna? The thing is 10' diameter and it's mine for the price of dismantling it and hauling it out of the present owner's back yard.

I'm thinking radio astronomy. Might be nice to make my own radio map of the galaxy. I'm guessing that this would work okay somewhere between 1 and 10 GHz... which means making a feed horn... which is easy enough to do.

What else could I do with this antenna? Other than covering it in polyethylene sheet to make a really big bird bath...

With 2 4 foot square alum panels 4 foot apart with circular
polarised 160M antenna in the capacitive field.All bands were S0
with 160M very active with strong signals. Could hear noise
and some static crashes from a distance but none that
affected S meter position. Early days yet but would appear I am
duplicating lower antenna of a stack since the S meter was at
rest when no signal present. Haven't got the rotor connected but
by listening to nets on 160M it strongly suggests it is directive
along the axis of the windings as expected.
Storms this coming week so I should be able to
determine antenna functions better. At present I have minimal
experience on the top band. Have not yet installed jumpers for
other bands nor installed a varometer at the feed point
but still have time before the snow flies

I said what I meant and meant what I said.

Our present formulas/equations leave much to be desired and apply only within narrow constraints of construction and design. However, when dealing with these antennas of strictly limited proportions and design (long wire, dipole, 1/4-1/2 monopole, etc.) these "approximations" are usually adequate ... stray too far from "conventional" and you find they begin to fall apart around the edges.

Despite Art`s disdain for amateurs, I`ve found solid information in the "ARRL Antenna Book". Mine contains Characteristics of a lambda/4 monopole which includes: "The current in a lambda/4 monopole varies practically sinusoidally (as is the case with a lambda/2 wire), and is highest at the ground-plane connection. The RF voltage, however is highest at the open (top) end and minimum at the ground-plane connection." The reason for this is already given in this thread.

Possible usage:
1) EME amateur comms
2) WiFi low power experiments (provided there is line of sight freedom)
I remember having seen a web site with reports (incl photographs) that some youngsters bridged a 125 km path using off the shelf equipment and dishes having a size like yours.

Hopefully you don't have just the dish but also a mounting pedestal and perhaps even a motorised system .

Additional Phase 3 satellites (AMSAT-DL P3E and AMSAT-NA Eagle in the
2009/2010 timeframe) are epected to be lauched in next 24 months -- plenty
of leaisurely time to rework and install a BUD for "S' or "C" band -- on a
budget.

Hi Tm
I have a 40 meter 4 square special on my web site if you would like to
check it out.

I also have guyed 80 meter verticals ,They are 1/2 the cost of the
freestanding ones.
Contact me if you have any questions.

Given past history with the SAT program, I would wait till assets are in
orbit and operational.

Still no harm in planing for such operations while installing the dish.

Having tons of patents means very little IMHO. It often just a PR exercise, to make it appear the company has worthwhile intellectual property.

I've seem some really useless patents.

> Look up Fractus antennas or subscribe to the quarterly industrial

> called Antennas.

Probably more worthwhile is something like the IEEE's antennas and propogation, to which I do described.

> The Fractus company was featured at the Antenna

And how many companies/individuals actually paid the $1000? I suspect most got in with special offers, or fees were waived completely. This is quite common - the published entry price of conferences is no measure of quality.

Hi Dave

NOAAPORT uses a satellite over the Equator, South of Texas to transmit satellite images in near Real Time. You can easily build a station for displaying good images of the Florida as seen from space.

Jerry

I went to the same place a couple of years ago when they had the
International
industrial computor show.Universities got a 15% discount that I
believe was
also available to overseas attendants other wise you had to pay the
full wack.
Relatives were allowed in free for the last 2 hours on the last day.
Exhibitioners paid the full wack for space but were allowed a few free
tickets
for commentators.
Don't you ever have anything positive to say?

Occasionally I'll listen to the online receiver made available by
K2JEU (http://www.ralabs.com/webradio/). Over the years he has used
various diffent antennas, ranging from longwires, to beams to most
recently a roughly 75 ft sloper. However, at one point he was using
40+ vertical from zerofive and it was vastly superior to every other
antenna I've see him use (excepting the beam, which doesn't belong in
the same comparison class). I almost couldn't believe it. I'd have
expected a large vertical to be pretty noisy, but the zerofive antenna
was incredibly quiet. I don't have space for such an antenna myself,
but I was awfully impressed with this one. It was really something.

You still haven't explained your comment regarding the high
impedance at the top of an antenna. Are you going to withdraw it?
My disdain is for those who put on the mantle of an expert and talk
like all is known about antennas without applying any logic of their
own

I thought about magnetrons... but not for communication. My idea is
to set it up as a radar station to measure the distance to the Moon. A
microwave oven magnetron operates at 2450 MHz, which is right at the
upper edge of the 13cm ham band. Unfortunately, magnetrons produce a
really dirty, wide output. Worse, being right at the edge of the
band, half the RF energy would be out of band.

I don't know if one can re-tune a magnetron by the addition of
external components; I'd like to get the thing down to 2.42 GHz to put
the emission in the center of the 13cm band. There are such things as
tunable magnetrons; but, they aren't found in microwave ovens, which
means they won't likely be had for free.

That said, I'd sure like to look at the output from an oven magnetron
with a spectrum analyzer. Maybe the output isn't as dirty and wide as
I think it is.

Yep, got the pedestal and the azimuth drive motor.

125 km at 2.4 GHz? How's that work? What were they bouncing the
signal off of? That's definitely further than line of sight.

Hi Dave

If you do build a system for receiving the NOAAPORT images, please keep me
informed about your progress.
I too got my dish free. The PCI card TV receiver was low cost. The rest
is computer and software. eBay is a good source of very good antenna parts
at low cost.
I am presently stuck due to my poor Linux skills, and Linux is used by the

guys who write the software (free).

Jerry

Hi Dave

Evidently there are places in or near Venezuela that have line of sight
adequate to get WiFi over 380 km.

I bought a used Hustler stainless steel ball mount with a spring at a recent hamfest. I installed it with a stainless steel Quick-Disconnect (QD2) screwed into the top of the spring. I found that the spring was extremely weak, and suspect it is not the original spring from Hustler.

I removed the spring and attempted to screw the bottom piece of the QD2 into the ball mount. It started OK, but wouldn't quite screw all the way in. Then when trying to remove it, it came out about half way and seized-up. I'm sure it wasn't cross-threaded to begin with, since it went in several turns without using the wrench.

Although it was hard to turn, I persisted until the QD2 started to turn more easily. Then I realized that the piece it was screwed into was also turning!

Does anyone have any suggestions on how to undo the seized parts? (Penetrating oil and freezing the parts didn't make any difference.)

nope, they are probably 'galled'. a condition that happens when you put
together two unlubricated stainless steel parts. essentially the pressure
of rubbing has spot welded the pieces together. this condition does not
respond to penetrating oils and other normal methods since the parts are not
rusted or dirty.

Unfortunately I would also say this is what has happened - I had the same experience with new replacement stainless bolts
on my bike - great, I thought, fit and forget, except when I was halfway through installing the first bolt I had to take it out and it seemed unusually stiff. I HAD to get it out so slow extreme force was eventually applied even if it stripped things, but it came out - a call to the supplier confirmed it must always be used with copperslip grease or similar to stop this very problem occurring.

I think the only solution may be force but very slowly to minimise heat causing more spot welds, else it will be a spark eroder or similar drastic action

Nick

A good power supply may clean things up a lot. I think you can rubber the frequency a bit by adjusting the B voltage and even the filament current. I think even the strength of the magnetic field effects it some.

How do you think the higher bands were conquered? It was always with
simple equipment that was cheap and easy (relative speaking), with
the more serious work coming later.

So before WWII, it was modulated oscillators and superregen receivers
on 56MHz and 112MHz. After the war, new equipment was available, and
there was a desire for pushing the limits (and laws came in at some

point to require better signals), and there was a move to crystal controlled transmitters and better receivers. Well, they really went together, since if you changed one, the other had to follow.

So that equipment got pushed up further, helping to stake out 220MHz and 420MHz. A lot of work was done on the 1215MHz band after WWII and even through the early sixties with the venerable APX/6 (I suddenly realize I may have gotten that wrong), which was a modulated oscillator for the transmitter, and it was often debated whether it was amplitude of requency modulated. The receiver was a superhet, but had a nice broad IF bandwidth, so it didn't matter how much the transmitter drifted. I seem to recall that the APX/6 was intended as an IFF unit, it gets triggered by radar and identifies itself as a friend, so nobody shoots at the airplane.

Newer techniques came along, more desire to push the limits, and that sort of thing was slowly phased out on the band.

But hey, it moved further up. In the late seventies, a lot of hams played with the 10,000MHz, using garage door openers, modulated oscillators and broadband receivers.

The further you go up in frequency, the more such cheap and simple equipment can be tolerated, since the bands get wider (well, until they get narrowed as bits are allocated away from amateur radio). So there is long history of both wideband simple equipment and narrowband DX'ing going on at the same time, albeit at opposite ends of the band.

But in reality, you dig up that article that was in "73" years ago that was about adding a phase locked loop to a microwave oven, which gives a nice narrow signal.

Congratulations and welcome to galling. What you've done is
inadvertently scrape off the protective oxide coatings from both
pieces and welded them together. Next time, try some anti-seize goop
in the threads. Incidentally, you can have the same galling problem
with aluminum and titanium.

You're correct that oil won't do anything useful. However, freezing
should work. Clean off as much oil as you can remove with some
solvent. Find someone that has liquid nitrogen. If that's difficult,
some dry ice. Freeze only the bolt, not the ball mount. A bolt that
size will take some time to shrink, so you may need to freeze it for
some time. My guess(tm) is about 2 hours. You could also warm up the
ball mount end, but it's probably not necessary. When the bolt is
nice and cold, do the brute force trick again. Don't beat on it with
a hammer or impact wrench as you're likely to shatter the bolt.

Another way is simple brute force. Build some custom vice jaws and
lock the ball mount in place. Flatten the sides of the bolt and
attack it with a big wrench and "torque amplifier" (steel pipe over
wrench handle). Beat on it with a hammer if necessary.

Another alternative is to just leave it as is. It's now a permanent
part of the ball mount. If it's sticking out too far, cut it back to
a usable length or install a threaded sleeve between the ball mount
and QD2 disconnect.

This is a relatively common problem with stainless. It will 'friction
weld' itself easily, and once that happens nothing seems to get it
apart. I've some interesting stainless bolts and nuts that this has
happened to, and have seen the effectiveness of the welding being
higher than the failure point of the bolt!

What is worse, it is difficult to predict when this will happen, but
it is important to use a stainless compatible anti-sieze compound on
stainless hardware.

I doubt you'll get it apart... If you want I can give you a picture of
a bolt end with a non-cross threaded nut--the bolt snapped rather than
the nut coming off (and it took a lot of work to break that bolt!)

You may have better success drilling it out, if that's an option.

Quietness isn't usually a good attribute of a receiving antenna. A dummy load is, after all, extremely quiet. Or do you mean that it had some magical property of separating the signal you wanted to listen to from all the others?

Don't have a Texas Bugcatcher antenna for you, but will offer some insight: You can find a good design for home brewing one at:

http://www.qsl.net/n1lo/antenna.htm

Scroll down to bottom and click on the 10 - 80M mobile vertical antenna. With these instructions, you should be able to build one that works even better than the original Texas Bugcatcher antenna. I did.

I doubt that it was a magical property, but it delivered more signal
and less noise than the other antennas he's used (at least while I've
been visiting his site). Hard to say what would explain it as many of
the details (grounds, radials, etc.) of his setup aren't set forth on
his website.

Aha! Living in Florida for the last 15 years has made me forget about
the mountains out west. Yes, you can definitely go line of sight up
to a few hundred miles if you have at your disposal an assortment of
mile-high piles of rocks upon which to mount the antennas.

I briefly went over the NOAAPORT web site. Looks like they have a
Windows flavor for the software, or maybe that's just a port to a
version that runs under a Windows emulator for Linux. Dunno. The
site wasn't too user-friendly - which just makes me want to build the
thing even more.

If you have any other online references handy for this project, I'd be
much obliged if you'd post them. For instance, in my review of the
site, I didn't notice anything about having to use a video capture /
TV tuner card - although I do have a USB version of one of those.

I shall post my progress, if and when. It's a project that's not at
the top of the list. First up is launching a weather balloon to
100,000 feet with a camera and a few sensors.

Thanks, Jerry.

When dealing with frozen parts, I use a torch to heat the parts up (if
they and their nearby parts will stand the abuse. Get 'em good and hot -
a red glow is not too hot - and back the screw out.

The obvious disclaimers as to the dangers of this method, such as red hot
metal burning things, and "Don't try this at home, kids!" apply.

I've been making em like that for years. It's a cheap way to get a
good
performing mobile antenna. They are also light, and require much less
sturdy mounts than the heavy all metal bugcatcher.
I don't use the capacity hat though.. Just a 5 ft whip over the coil.
My first one used a 5 ft CB whip. My latest one uses a 6 ft 20m
hamstick
as the glass mast. The coil takes about a ft of room at the top of the
stick,
so it comes out almost a perfect center load with 5 ft under the coil,
and
5 feet over it.
For industrial strength use when parked, I screw a 3 ft hustler mast
to the
base of the glass whip. That raises the coil to 8 ft above the base
and a 14 ft total height of the antenna.
Both of mine work all bands 80-10 using various coil taps, or
different
length stingers for the higher bands.

Heat the ball mount with a torch to cause it to expand and melt some
candle wax into the threads as a lubricant (watch for fire). I don't
think you need red hot, just get the mount to expand enough to break the
bond and apply force to turn the QD threads.

Joe & All-

Thanks for the information and suggestions. I understand stainless is a poor conductor of heat. I might try a combination of freezing the parts and then using a torch on the outer piece to increase the temperature differential.

The female threads may have been tapped prior to crimping that piece to the top shell of the ball, and the crimping process could have distorted the threads near the crimp. If I had known about the likelihood of "galling", I might have tried re-tapping the threads prior to installing the QD.

Hi Dave

Hector has most of what is needed to make a low cost PCI TV receiver work
for NOAAPORT. The Twinhan PCI cards are affordable thru eBay and etc.
I thought I'd get more help from the "regulars" on the Yahoo NOAAPORT
site, but am now disappointed. And, I am slow to learn the Linux (Fedora)
that is used to reduce the data.
I want you to learn how to make images so you can teach me. I did go out
and buy parts and assembled a computer for Fedora. Now I have to learn how
to navigate in it. I too have found the"instructions" a bit difficult for
me to understand. But, Hector's instructions
(http://www.hwic.net/projects/weather/noaaport/) are quite direct and
easy to understand.

JERD

There is a specific instrument called a three terminal earth impedence meter used to measure earth impedence. Three electrodes are driven into the ground at set distances and the earth impedence is measured directly by the meter.

This equipment is intended to ensure that a sufficiently low impedence exists for safety electrical earth connections to operate fuse, circuit breaker or residual current devices reliably. Most professional electricians will have such a device (or at least know where they can get hold of one).

An earth connection that is satisfactory for electrical supply safety purposes may not necessarily be adequate for RF use.

When nobody else comments, I do.

Yes, I actually bult several LPDAs from the LOGPERIO
calculations and they work perfectly

Caution:
Each LPDA has certain Z variations over the
whole frequency range.
1 : 1.7 is very well done.....! 1:2 is still good.

Do you have the LOGPERIO version with the
antenna graph display?

Size and farness in spase are the same entity; there is no matter
without them. So warped size is the same as one component of warped
matter, in the potential-span relations.

Just how precise a measurement do you want to make? You could do quite
well using a 100W 2m SSB rig and a decent yagi antenna and some signal
processing software.

See, e.g. http://home.earthlink.net/~n5bf/eme2.html

>
> I don't know if one can re-tune a magnetron by the addition of

> That said, I'd sure like to look at the output from an oven magnetron
> with a spectrum analyzer. Maybe the output isn't as dirty and wide as
> I think it is.

it is quite dirty, even more so in an oven because:
1) it's fed by a half wave voltage doubler, so it's pulsed at line frequency
2) the voltage waveform is hardly nice and regulated
3) the temperature of the tube changes during operation

Why not build/buy some small no-tune transverters for 3.4 or 5.7 GHz and
use those. At least then, you can do coherent processing over some
reasonable time span, and what you lose in raw pulse power, you pick up
in processing gain.

The beamwidth of your 10ft dish at 2.4 GHz is going to be pretty wide,
so you're illuminating a lot more than the moon (which is wasted power).

In absolute terms, on receive, the fraction of the signal power received
from that power which hits the moon will be the same (same physical
aperture.. gain in dBi is larger, but that's just because an isotrope
has smaller aperture at higher frequencies).

So, your goal should be to illuminate JUST the moon (and a bit more to
cover pointing errors). Beamwidth is approximately = 70*wavelength/d.

So
GHz m deg dBi
2.4 0.125 2.9 35
3.4 0.088 2.0 38
5.7 0.053 1.2 43

Given that you want to light up the moon with the same power, at 2.4 GHz
it will take 8 dB more than 5.7 GHz.

Since the moon is about 1/2 degree wide, even 5.7 GHz is a bit low for a
10 foot reflector.

There's a little more than this to the whole problem, but, in general,
if what you want to do is measure the distance to the moon, a radar
built with an oven magnetron probably isn't the best way to go about
doing it.

I have replied in detail off forum but to summarise, the consumer earth
connection is provided for electrical safety purposes to reduce the chance
of lethal shock from the supply and to ensure that circuit protection
devices operate to prevent the risk of fire under fault conditions. It is
not provided for radio applications.

Having the best earth in the world can all be negated by then running a long
earth cable up the wall of a building to an upper storey radio installation.
Keep earthing runs as short as possible and ideally have your radio
equipment installed on the ground floor or in a garden shed.

Some people just get there kicks by doing thing with bubble gum and bailing wire, on the other hand you sound like an epoxy and tie wrap kind of fellow.

Hi Helmut!

Many thanks for your comments.
NO, I had the 'default' version, in which I'd made some layout changes,
but I really like your version much more!

Thanks for sharing your experience - now I will certainly try one
(although building antennas also gives lots of fun!).

As soon as I will have one completed, tested and installed (for DVB-T
use, called 'Digitenne') I will leave another message sharing my
experiences.

Copper-clad rods will greatly outlast galvanized rods.

Reg Edwards, G4FGQ had among his trove of free programs one called "Earthies", if I recall. Reg is now a silent key (SK) but his programs survive and are still available free.

Search on: K3HRN site with G4FGQ programs. The site will appear. I had always wondered what Reg looked like. His portrait is on this site.

Best regards, Richard Harrison, KB5WZI

Thanks a bunch for pointing that out. I'd wondered about the relationship between beam width, reflector diameter, and frequency.

Now that I think about it, doesn't focal length or focal ratio play a part as well?

I don't suppose you could point me at a decent reference for this stuff, could you? I've found that Google (i.e., the web) is somewhat lacking when it comes to explanations - especially accurate ones - of where those nifty approximation equations come from.

>There's a little more than this to the whole problem, but, in general,
>if what you want to do is measure the distance to the moon, a radar
>built with an oven magnetron probably isn't the best way to go about
>doing it.

So noted. The goal here is not so much to do it the best way possible, but rather to see what kind of results I can obtain using the scrap (i.e., free) materials I have available.

If I were after accuracy, I'd point a laser at the corner reflectors left by the Apollo missions. 8^)

I assume you are trying to measure the low frequency resistance of the electrode. The minimum reliable method is known as the three wire fall of potential method... Google for it.

Galvanised electrodes are less consistenn that copper clad electrodes, so you may find repeated measurements over time vary more than accounted for by soil characteristics alone.

Depends on the level of detail and backup you want. There's a EW
Handbook at Point Mugu Naval Air Station, you might be able to find it
with google.

W1GHZs online book is at: http://www.w1ghz.org/antbook/preface.htm

Sure, I understand..

It's just that MO Magnetrons are such ragged edge cost sensitive items
that they spend absolutely nothing on making them good transmitter
components. After all, all they have to do is heat stuff, cheaply.

Even if you have a design from, say, 20-30 years ago, I suspect that
modern tubes aren't going to be as suitable.

I did see a clever design where they took a whole array of MO magnetrons
and injection locked them to build a microwave weed killer. Microwave
Journal, October 2005.

http://www.mwjournal.com/journal/article.asp?HH_ID=AR_113

Enjoy...

Hmmm.. That's a nontrivial thing.. BUT, you could do (maybe the first)
optical EME contact on the 470 THz band.

Source record: 35162

I am looking for ways to improve my receive for 2-meter SSB weak signal work. I am running an Icom 706 MkIIG and a M2 5WL yagi. I understand mast mounted preamps bring the signal up significantly.
Doe any one here use one for 2M SSB? What are your experiences?

Thanks
Russ

Russ, you may find the article at http://www.vk1od.net/gt/index.htm of interest. It includes a model framework to allow you to calculate the improvement that you would obtain from a LNA.

One thing to bear in mind is that laboratory tests of LNAs do not usually revean the amount of noise that will be generated in the LNA as a result of intermodulation processes... so it is unlikely to perform quite as well as indicated. At the same time, the same issue exists for the transceiver.

The good thing is that your 5WL Yagi will have a good deal of selectivity whereas it is certainly lacking in the '706IIG and in many of the lower cost preamps (no money wasted on filtering).

At the end of the day, it depends very much on your own noise environment, noise generated by IMD in your radio, and the equipment configuration. Hams tend to regard ambient noise as not an issue on 144MHz, but it probably is if you live in a residential area... and high ambient noise will limit the benefit of a LNA.

Owen

Russ,

I have used both Landwehr and ARR preamps for 2 meter SSB. One of the major issues is how much coax, and what quality, you have. Another is the quality of the preamp which you have in your rig. In my case, I have about 70' of very low loss coax, almost hard line in performance. The preamp in my rig is fairly good, and the result is that there is little difference in performance, though there is a slight nod to the mast mounted unit. Lossy coax would definitely tip the choice to the mast mount. And in fact, on 70 cms with equivalent components, the mast mount is the clear winner. Beware of units which don't give you noise figures, as that is normally much more important for weak signal work than gain.

Am just today experimenting with satellie in-line amplifiers,
the variety for home sat reception, cheap, small.

Some range from 100 MHz to 2,4 GHz, some have limiting
filters on the input which you can easily remove or modify.

Works.

There are 3 factors that determine if a preamp will help: does the radio have poor sensitivity to start with, do you have significant feeder loss,and how high is your ambient noise floor.

Taking the first and last together; no matter how good a pre-amp you use it will be of no help if you have a high ambient noise floor to start with. This is governed by where you live, quite country locations are obviously much better than cities. As a quick check, see on ssb if your noise floor drops significantly when you disconnect your aerial.
If it does then it is worth doing a better check where you compare the noise between the aerial and a good dummy load. If the noise still drops significantly then you are limited by the external ambient noise and all a preamp will do is amplify this noise. If is does not change then you either have a quite location or a noisy receiver.

If you are not limited by external noise then a preamp may help if you have a lot of feeder loss, but the pre-amp must be at the antenna end, and not the radio end, to improve things (unless you have a very very deaf receiver).

In any case keep the gain of the preamp as low as possible that is still consistent with improving the noise floor in order to limit problems with receiver overload.

It may not be worth the bother for low power. The receive preamp won't help
them hear you any better. At a KW output, you would want to do it for sure.
Meanwhile, make sure you are using low loss coax. That will help both
receive and transmit.

I suspect the preamp makers would portray this as providing more system engineering flexibility, letting you, the system builder, decide how much filter selectivity (and corresponding loss/degradation of NF) you want.

After all, if you were doing EME with a big array pointed up into the sky, selectivity might not be such a big deal, but absolute lowest system noise figure might be.

Hi, Fred.
Retapping won't help, unless you have an oversized tap. What will help is using an adjustable die on the male part and squeezing the die down quite a bit before using it. This will give you a less than 50% thread engagement, but will still be enough for your antenna. Antisieze compound is the real answer. Also, if you ever need to drill and tap stainless, use the next larger size drill bit for the tap you are going to use. Otherwise you will surely break the tap. I have scars to testify to learning that!

Good luck,
Paul KD7HB

Paul-

I understand there is also a "thread chaser" tap, which might be slightly oversized. I was thinking about the distorted threads being cleaned up by re-tapping. Perhaps one of the local hardware stores will have a 3/8-24 tap, as well as some anti-seize compound.

I contacted New-tronics by E-Mail. They also suggested heating the female threaded part with a torch. They apparently have encountered the problem before, but their instruction sheets never mentioned it or the need for an anti-seize compound.

Also, New-tronics does not sell parts, only complete assemblies!

I used one of these "bullet" preamps once upon a time and the the
improvement in reception was amazing, too amazing.This was a give away
clue that my coax was bad. When I cut the bottom end off about a cup
of water came out of it

Russ- You may improve your senseitivity to a degree, with a preamp,
but it may (or may not) be worth the effort. As the mast mounted
preamp will establish your Rx noise figure, but, the ONLY advantage
from the GAIN of the preamp, would be to overcome the (Coax Loss,+
the Xcvr front end Noise Figure)-
This assumes that the preamp has a Noise Figure LOWER than the rig
, as Lower loss (hardline)coax might be more beneficial!
- the rest of any gain will only
make your receiver subject to front end overloading , from nearby
STRONG signals! Futher, you must have SOMETHING to delay the
transmitter from keying (a " sequencer"), or you may destroy your
preamp, by transmitting into it! Question? What is the Fastest
fuse you can get? Answer: a Transistor! Another way to increase
sensetivity, is to narrow your receiver band width . Halve your
Bandwidth, gain 6 dB increase in senseativity (X-4). And, as a
reliatively good test as to HOW MUCH the preamp will improve your
reception, try this test: 1) attach a 50 ohm non inductive
resistor to your antenna connector, and note your NOISE LEVEL/
S-METER. 2) Now replace your dummy load with your antenna.
Did the noise /or S-METER INCREASE? If so, you are most likely
receiveing at your maximum senseativity. (IF the noise level stays the
same, you MAY make an improvement to your system, tho, HOW much,
is hard to say! Hope this helps-- Jim NN7K

if the radio is happily putting out its rated power then don't touch it,
keep operating! remember, too low an swr can kill you!

My article contains links to two spreadsheets, a basic one and an
enhanced one. The enhanced one contains macro functions that calculate
the Sun's position from the time data recorded by NFM (and your location
data). Of course, you need to make sure your computer clock is
syncronised before taking the measurements. The link to the enhanced
spreadsheet is in the Links section of
http://www.vk1od.net/nfm/applications/AntennaPatternFromSun.htm .

The spreadsheet uses a set of macro functions derived from the NOAA
calculator ant published by the Department of Ecology, Olympia WA.

It is a relatively simple matter to measure the ambient noise level. The ambient noise level is one of the factors that is vital to understanding the benefit of a given preamp.

A simple test along the line of what Jim describes above, but leading to a quantitative figure for ambient noise is described at http://www.vk1od.net/sc/anc.htm , including a calculator to perform the calculations.

Not many hams can tell you what their ambient noise level is on 144MHz, but lots will wax on about the relative importance of LNA gain, LNA noise figure, and cable loss. If you don't know the ambient noise level, you cannot answer any of the other questions.

Note that ambient noise may change by hour of day and with antenna pointing.

Hi Jim,

I suspect that was a bit tounge in cheek! I guess the manufacturers have done us a bigger favour with hand helds in making them lighter by minimising filtering.

If you want to fix an IC706IIG's front end selectivity here in Oz, one of those Canadian filters for about $250 + $300 shipping is just the go. Wait a minute, $550 to fix a $1000 radio's performance, and on just one band... I don't think so.

I wrote an article on the performance of a modestly priced kit 144MHz amplifier in the real world (as opposed to in a shielded room). I have devised a test configuration that asseses what I term the 'realisable sensitivity' which may be quite different to the specs derived in a shielded room. The article is at http://www.vk1od.net/gt/144LNA/index.htm
.

The article also looks at the G/T improvements expected from other configuration changes like a higher gain antenna and low loss coax, and whether the preamp is located at the masthead or transceiver. Of course, it all depends on one's own configuration, but the tools are there to model a specific configuration.

What are you feeding your dipole with? Coax or ladder line ?I found that if
you use 450 ohm ladder line for your feed the length of the feed line can
cause you problems . What kind of rig are you using ? BTW welcome to the
group !

Go up and down in frequency a few hundred KC and see what the swr is in
several places. Depending on the feedline and length it should probably be
lower at some frequency near 28.4.

That's marginally OK. What is the SWR at 28 MHz.?
What is the SWR at 29 MHz?

Hi Owen

I use a free program "APTDecoder" for monitoring satellite location.
That program includes a "Flat Earth Monitor" in which the Sun and Moon are shown. A "mouse pointer" on either the Sun or Moon will give the location and Az-El from your location, in real time. I have never used the data to point my dish, but, if the data is erroroneous, Id like to know where is wrong so it can be made better.

Thank you Owen, Jim, Alan, Tam, Helmut, Jimmie and Jeff for all of the great responses. I guess I should have provided more info in the first post.

My station is in the foothills of Northern California at about 1200' elev which is somewhat rural and is relatively quiet most of the time. Power output is up to 500+ watts on VHF and the feedline to the antenna is about 90' of 1/2" Andrew Heliax hardline. The antenna is 43' up. Using my previuos yagi, an M2 2M12, I worked stations as far as Oregon and San Diego.

Good points on noise figures versus selctivity while considering noise floor of the rig. I did try chercking the receiver noise with a Microlab dummy load installed at the radio then with the antenna conneted. Yes, there is more noise with the antenna connected. What is interesting is that with the dummy load connected, the noise was just higher than wit the ope SO-239 at the radio.

The responses have also steered my attention toward the 706G itself. While it has been a great radio for several years, and offers fairly good performance on many bands, designing this and similar multi-band radios must include compromises. Perhaps I should be looking toward getting a rig more tailored
to the 2m band and SSB mode? The Icom IC-910H comes to mind.

At this point, I will look more closely at the antenna/feedline system I have and look into a better performing radio before investing in a mast-mounted preamp that will introduce more connectors in the feedline and which will likely require more maintenance as well.

Thanks again.
Russ W6OHM.

Try transmitting up and down the band to see where your lowest swr is.
Then you can shorten or lengthen the antenna a bit to get a low swr in
the 28.4 mhz range. If you can't quite get it to 1:1, coiling the coax
at the feedpoint, 4 or 5 turns about 6 inches in diameter can get you
pretty close to 1:1.

2:1 isn't bad, but you're probably not getting full power output if
your rig is solid state.

The higher the ratio of noise from the antenna to noise from the dummy load, the less likely you are to get much benefit from a better receiver.

You need this ratio which tells you the ambient noise (albeit with IMD noise rolled in) to predict how much a LNA or better receiver will improved things.

Of course, by 'improve' I mean better S/N ratio, not simply higher S meter deflection.

Alternatively, you suck it and see.

> is interesting is that with the dummy load connected, the noise was
> just higher than wit the ope SO-239 at the radio.

I assume that was to say "with the open SO-239".

I don't really know what you can conclude, because you don't know enough about the radio when the input jack is o/c.

Hi Owen

The APTDecoder program is written by Patrik Tast who lives in Finland.
The main reason for anyone using the program is to decode NOAA weather satellite signals so images of the satellite's view of the Earth, from orbit can be displayed on computers by amateurs (in real time).
I mentioned the "Flat Earth Monitor" in Patrik's program because it seems to always be a source of Az-El and Lon-Lat for Sun and Moon position. You tell the program where you are and the program tells you where to point. I mentioned the "accuracy" because he is interested in knowing about any improvements he can make to his program. Patrik does not charge for his program. He is an amateur, interested in providing good data, and I consider you to be a good critic.

If you can hear - and be heard and the band is open - then you're ok.
If you can't hear or get heard - raise the antenna and try again.
Good swr does not automatically mean a good antenna.

The without even realizing it before, I have a "fractal" antenna in my attic (it looks like a G5RV turned into a square wave) :-))

I'm sure my "fractal" antenna has no lobes and has a fairly high radiation angle but it works fairly well. Maybe I could patent it :-))

The only conditions for issuance of a patent would be that it is different
than prior art and that it transmits radio waves with a radiation efficiency
greater than 0.0%. That fact that there is a patent does not mean that a
product exists for which a successful marketing business model can be
created but then again, successful business models have been created on
'inventions' even less credible than fractal antennas. The "pet rock" comes
to mind.

It's probably too long, but check it at 28 & 29 Mhz. If the SWR at 28 is
better, it is too long; if the SWR at 29 is better, it is too short.
Assuming you are using 50 Ohm coax, no reason you can't get it below 1.5:1.

Hi Jerry,

That is flattering, but undeserved I am sure.

There are a lot of calculators on the 'net for giving the Sun's position at a place and time, and they use varying algorithms for more or less accuracy.

The routines I used in the spreadsheet were unashamedly the work of some one else, the chap who converted them to VBA and the original NOAA javascript routines behind their page at http://www.srrb.noaa.gov/highlights/sunrise/azel.html . I have accepted they were good enough for my application, and they seemed quite close to another navigator application that I have.

If he has room for it, this may very well be the best way to go. Gets away from finding an amp that can take 500W on transmit, and does away with complicated sequencing, which, if not done right could blow the amp if you accidentally use VOX. For starters, replacing the 706 will probably result in the best fun factor.

==========
When SWR is 2:1 the reflected power is only 11% of the tx output power,
which will hardly be noticeable at the receiving end .
Even when SWR would be 3:1 only 25% of the transmitter power would be
reflected , still resulting in only a fraction of an S-point at the
receiving end.
But a low SWR will make the solid state PA of your radio feel happier !

Frank, your analysis ignores the fact that the PA may deliver other than its rated power into the actual load, it could be higher or lower power, but in radios that incorporate VSWR protection of the PA, it is most likely to be lower, and at 3:1, substantially lower.

VSWR protection helps protect radios operated by operators with the view that 'anything works'.

To me, 2:1 seems a bit poor for such a simple antenna and probably readily capable of improvement to 1.5:1 or better. More importantly, the OP might expand their knowledge in the process.

The original description was scant on information about the configuration, and I guess that sometimes, knowing how to describe the configuration / problem is the first step of knowing how to solve it.

Others have identified missing elements of the description, the use or otherwise of a balun is relevant in indicating the extent to which common mode feed line current plays a part in determining the load presented to the feedline.

And, really, what precision do you need for pointing/plotting?

Presumably folks are looking at fairly wide beamwidths (so that the sun
size (1/2degree) is a small fraction of the beamwidth)
5 degrees?
1 degree?

Get into that 1 degree range and you need to start taking into account
stuff like the non-spherical earth, and stuff like the sun's apparent
diameter (which is different for radio and visible light, as well as
varying with the distance).

Heck, you might have to worry about whether your local gravity vector
(presumably what you used to set the elevation zero point) is
perpendicular to the geoid surface used for the look angle calculation.
And, whether your zero az is actually the same north as used in the look
calculation (as opposed to, say, aligned to Polaris at some arbitrary time)

(FWIW, the calculations behind the USNO page do take a lot of this stuff
into account)

Jim, I suggested in my article that the Sun technique was most suited for beamwidths down to about 3 deg. As you have noted, there are a large number of other factors that become relevant at small beamwidths, and the most significant I think is the beamwidth correction factor to account for the Sun's departure from being close to a point source, then as you note the frequency dependent diameter of the radio Sun and the distribution of the Sun's intensity.

So, down to 3 deg, the macros and formulae in my spreadsheet should be more than adequate.

My thinking was that if you have a narrower antenna beamwidth, you probably have sufficiently high G/T to use one of the radio stars which will have much lower diameter.

Tam, that would be great, but I live in a community with CC&R's and antenna restrictions. I was barely able to get permission for my single yagi by using 911 and the Loma Prieta earthquake as bases for arguments. I really don't want to push the issue too hard. I do agree that looking into a better radio is probably the first step. If they made a VHF/UHF radio with similar features to the Icom 756 Pro-III, I'd grab it in a heartbeat. Otherwise, the antenna and feedline will be optimized as time permits.

There are two basic types of taps: thread-cutting taps and thread-forming taps (also called "roll taps"). They work just as described... the former removes material to make threads, while the latter pushes material to make threads. Roll taps are used to make threads in soft materials (mainly aluminum, copper, and the like) but can also be used to chase threads that have already been cut/formed. Your local machine tool supplier or McMaster-Carr (http://www.mcmaster.com/) or MSC Industrial Supply (http://www.mscdirect.com/) should have them.

From: JERD <jedunk@REMOVEbigpond.net.au>
Message-ID: <bBWTi.4367$CN4.3308@news-server.bigpond.net.au>
Source record: 35109

I am wanting to install an earth stake/rod for a new antenna system. The problem I have is that the 'best' position for this falls somewhere near where our underground sewer pipes run. As accurate measurements that I can ascertain from the engineering drawings puts it somewhere within 3" (75mm) of this sewer pipe and I am not prepared to rely on the accuracy of the drawing and or the pipes installer and end up puncturing the sewer pipe!

I could drill a hole in a concrete path and sink the earth stake/rod through the concrete path and this raises the question! Is this likely to be a good position to put an earth stake/rod seeing the ground under the concrete path would never get seasonal rain and in fact has not seen seasonal rain for some 30 years!

Does this matter or is good old mother earth still going to provide a good earth for my antenna system?

Sure would appreciate some advice regarding this.

VK5JE - from way 'down under'!

I think you should look at an alternative ground system. For example,
a copper "matt" laid over the sewer pipes instead of between them.

If you have a decent earthworm population, you can lay it down on the
ground and in a few years it will be buried. I'm assuming that you
want something for HF work, so the size of the "squares" can be fairly
large, there is no reason to use screening.

If you are looking for an electrical saftey ground, for example as
lightening protection, then a horizontal ground rod will do. Bury it
below the "frost line" and you should be ok.

Geoff.

Hello, and you make some good points, Roy. (I always pay close attention to many of Steve Best's IEEE papers on antennas). While I've not analyzed or experimented with antennas based upon fractal patterns I have always wondered whether broadband performance could be achieved since fractal patterns would repeat with electrical (frequency) scaling. Granted, these patterns unlike, say a logarithmic spiral, would only repeat at discrete values. Your comment above indicates this is not the case, however.

Frank, I know that you know this, but I want to comment to the group...
Assuming the transmitter does not fold back, the 11% reflected power will not change the signal strength... The reflected 11% will be 88% radiated on the return trip (minus any line losses) and 88% of that on the next round trip, etc... So, in the end the decrease in transmitted power is only a fraction of 1% for feedlines with low losses to start with... W2DU's very readable book REFLECTIONS, would be a good place to start for those who are a bit hazy on transmission lines, reflections, conjugate mirrors, etc....

Now, if we take transmitter foldback into consideration, we will need a lot of information about the various rigs before we can even begin to discuss how much a 2:1 SWR will change radiated power...
Personally, for a situation where there is SWR on the line, I prefer a DX100B - it's pi-net could not care less and will still put out full power into 2 or 3 to 1... As well as some more modern rigs such as TS-830, etc... Tubes have a lot going for them... The Omni series of solid state rigs from Ten Tec also do not fold back under 2:1, though 3:1 does have some effect...

cheers ... denny / k8do

That will only be true IF the Tx output stage has an infinite SWR looking back in to it, AND the reflection is in phase with the forward signal. In practice this will not happen. In fact the re-reflected signal may be 180degrees out of phase and so diminish the signal by its total value. The real story is that a much smaller proportion of the reflected signal will be re-reflected and the phase will depend on the system in use.

In reality the impedance of a transistor o/p stage looking back in will not be too far away from 50 ohms due to the broadband matching networks.Some transmitters that I have worked on even had a spec on the impedance looking back in, a real pain to measure under full power conditions.

If, as reported, more than 99% of the output power of a transmitter ultimately is absorbed/radiated even by a mismatched antenna system, then why would a transmitter need power foldback for such loads?

I would hope that it's for electrical safety as a ground rod has little use as an RF ground. At best it's no better than an 8' ground radial. A ground for lighting and electrical safety is a good thing but should be used in parallel with an RF ground (radials or ground mat) for antennas.

Gentlemen
In constructing "slow wave" antennas for top band I am finding that a
wavelength in equilibrium is a bit longer than expected.
As I am using large diameter formers for circular radiation I suspect
the reduction in number of turns is the reason.
Does anybody know of a turns versus length graph has been made for
this phenomina and where I could find it?
At present I start with scaling up a Tesla coil as a starting point
but that is becomming somewhat laborious after winding a few antennas.
(I will be placing a photo of my antenna on my page in a few days)
TIA

True if a match has been achieved by a network.
A 100 watt source will provide 112.4 watts of forward
power with 12.4 watts of reflected power.

Power delivered to the load is 112.4w - 12.4w = 100w

Not true where a 100 watt 50 ohm source is not matched
and provides 100 watts forward with 11 watts reflected.

Power delivered to the load is 100w - 11w = 89w

Here you go, Art. Equation 32 and Fig. 1 should be within
10% of what you need assuming your device meets the test
equation boundaries given between Equation 31 and Equation 32.

Thanks so much for that article by the most formost
scientists on this subject.
I have not made things easier on myself lately as I
have migrated to tinned
copper braid for extra gain which obviously increases
the slow wave length somewhat because of the added
indunctance which some would considered as being cancelled Hi.
At first I was considering the actual wire length
in the braiding b ut that influence became little
compared to the current pertabutations. Also have
found that the standing waves do not completely
disapear until the top band radiator is up at a
one wave height which was a bit of a dissapointment
but still acceptable at 850 feet.
Thanks again for what appears to be a jewel
Art Unwin KB9MZ....XG....(uk)
Can't wait to add a flyback transformer so I can
make a radio wave missile launcher.

Sounds like you are working on a self-resonant coil
and need to know the length of time for the current
to flow from end to end.

Both sides of the argument are wrong on that one.
The current does not jump from one end of a coil to
the other in a very small number of nanoseconds as
one "expert" has asserted which implies a VF close
to 1.0. Neither does the current follow the wires
directly round and round the coil as asserted by the
other side which would imply a VF around 0.01.

The actual measurable VF of a coil seems to be just
about double the round-and-round argument side as
there is indeed some coupling between adjacent coils.
A typical 75m Texas Bugcatcher 6" dia, 6.5" long,
4 tpi coil has a VF of around 0.02 making it about
40 degrees long at 3.8 MHz.

According to B. Whitfield Griffith, Jr. in "Radio-Electronic Transmission Fundamentals" on page 351, a single ground rod introduces about 50 ohms to an antenna`s resistance. He says contact resistance to the soil may be very low but the loss will be in the large area of soil surrounding the rod. Radials are the answer to the low soil conductivity probl;em.

A broadcast grounding system of 120 radials, each 1/4-wavelength long, may have a ground resistance of about one ohm, as shown in Fig. 43-2 on page 353.

Best regards, Richard Harrison, KB5WZI

"Increased gain?"

That is correct when considering "power gain" of an antenna, which is, power into some reference antenna / power into the gain antenna in the same direction.

"Directive gain" of an antenna has nothing to do with losses.

No Cecil you are following a fatal aproach by using
lumped loaded circuitry which is a no no when measuring current speed.
Especially when you are following a path of zero standing waves.
To obtain a voltage doubling you can only solve by using
distributed loading aproach where a single wire has approx length
when measured close to the ground short of two wavelengths .
Unfortunately by using braid to get extra current perbutatation
the length extends quite a bit longer even tho braiding electrical
length is longer that the physical measurement.
Ofcourse the introduction of a flyback transformer would be
exciting but we must not run before we walk

I recall the Fractenna man, Dr. Chip Cohen, used to define fractals as self similar elements assembled to cover a wide range of frequencies.

That roughly conforms to Kraus, "structures that preserve their shapes at different scales."

Kraus` conical spiral and log periodic antennas in Figure 310 on page 68 of the 3rd edition of "Antennas" also seem to fit the repeating structures of different scales designed to produce very broad bandwidth with moderate gain and might be called fractals.

I think you cannot rely on calculating the braided length as being longer than the physical length. While it is true that the braided wire if unravelled would likely be considerably longer, RF waves propagate along the surface of the wire. They will jump from one wire to the next where the braids cross, following the path of least resistance. You would probably need to use braided Litz wire, where each strand is individually enamelled to achieve what you appear to be trying to do.

Jerd,

Nothing here stated AC protective ground (which comes from the earth pin in your three wire power socket) or lightning ground.

You have identified that you want to attach the second output terminal of the AH4 to the electrode. The proposed electrode (whether or not it is throught the path) is likely to have a resistance that results in a low antenna system efficiency at frequencies where the radiation resistance of the antenna is relatively low.

The article at http://www.vk1od.net/InvertedL/InvertedL.htm models a scenario that is probably quite similar to that which you are considering, and discusses points relevant to the design... could be worth a read.

Now, there will be a body of opinion that it doesn't matter what you do, you will still get QSOs, that it therefore 'works'. It sounds from your question that you are more interested in that shallow level of engagements, so read around.

I wrote another article on a minimal setup again with an AH4 and end fed wire, it is at http://www.vk1od.net/NaroomaEFW/NaroomaEFW.htm .

By all means, drive an earth electrode as you have proposed principally for lightning protection (though I would use a 2.4m copper clad steel electrode), but run at least a couple of (untuned) shallow buried bare copper radial wires from the AH4. Locating the AH4 remotely from your shack and house if you can will reduce the RF intensity in those places and reduce EMC problems.

Catch you on air sometime.

Owen

Nope, I'm arguing against that approach, Art. Some
"experts" seem to like lumped load concepts but not
I. Dr. Corum warns against using lumped load concepts
for large coils and I agree with him.

I see where you are coming from but braid wicks like mad so a good
dose of quick drying polythene varnish solves that problem IF it were
to
occur, tho the current will not jump but follow the path of resonance.
What I am doing now is a combination of insulated wire with doped
braiding
and it appears so far that the braid is required to be much longer.
When time permits I will make seperate models using wire and then with
braid
on a higher frequency where the single wire form is easily calculated
as a datum
As far as Litz wire goes there is a frequency transition line when you
use that
(skin factor) so I am not anxcious to introduce another variable or
spend
the required extra money.
Regarding travelling on the surface of the wire I have often pondered
that the use of braid for grounding wire is subject to question
compared
to a copper wire or ribbon. As I see it the braid is heavily inductive
even tho it has the appearance of the field balancing out since the
current must still traverse the windings, but that is another subject
all together
deserving of its own topic title.
I know it may sound wierd but I am trying to slow down the current by
half so that
for the tank circuit I will have four pulses of energy release over
the existing
two.Single wire windings are just a hair to fast to accomplish that
In other words double the power of a particle generator which is
what
radiation is all about, at least in my mind, since I see the
attributed gain of a helix

being controlled by the voltage increase in sync with the current flow
which I see as
not quite correct when using single wire since. I am still seeing
standing vaves which are small
but does not prevent full traverse of all amateur frequencies using a
single antenna with a
variometer for use when resistance levels drop below 20 ohms.
It just blows my mind how just applying a time varying field to a
static
field is providing so much more info with respect to radiation
assuming
one has a true understanding of what equilibrium is really all about
and which the majority deride
Cheers

Good for him. It appears that constant use of lumped circuit analysis
is gaining more votes against true science of today especially in
amateur
radio. Soon it will be promoted to a Law disregarding that it is
only theory based. Something akin to a poll

Ahhh, ya namby pambys... My open wire feed line can lick your coax!
And the tuner is a conjugate mirror to boot...
nyaa, nyaa, nyaa...

denny / k8do

Oh yeah, and to add something constructive for the one questioner:
Foldback on transistor amps is to prevent RF voltages rising high
enough to puncture the transistor junction...
Tube radios with pi-net or pi-L tanks had enough matching capability
to handle significant impedence mismatch compared to broadband
transistor amps... Today, that function is served by autotuners, etc...

My homebrew Field Day rig monitors only the "forward power" with a single directional coupler and adjusts the output level to keep the "forward power" constant. That rig delivers 83% of the power into a 2.38:1 SWR load as it does into a 1:1 SWR. This represents a 0.8 dB power reduction. Big deal.

But my 25 year old Icom 730 delivers a full 100 watts to the output regardless of the SWR up until it starts shutting down at around 3:1. For example, with a 2.38:1 SWR, the "forward power" is 120 watts and the "reverse power" is 20 watts. Aren't modern rigs able to do this, or have they gone to the simpler system like I use in my homebrew rig?

Umm a velocity factor of .50 might be attainable with a variation on leaky coax... Some of the cheap stuff is already as slow as .66...
Off the top of my pointy head braided wires wrapped on your form (same as you are currently doing) then potted in an appropriate dielectric material for filling the braid interstices should slow things down some more... The question extant is what material for potting (or for adding to your potting resin) will further slow progression of the wave front along the braid...
We know that solid polyethylene dielectric on coax results in a lower vf than the foamed materials.. So it appears that denser material results in slower wave progression... Perhaps UHMW, or similar might suffice...
Other thoughts come along, such as a flat ribbon with a deeply embossed pattern then filled with dielectric might be slower than braided wire... Or even a ribbon of screening material similarily filled...
Dunno... Interesting problem...

> they gone to the simpler system like I use in my homebrew rig?

Roy,

Modern rigs often employ a range of protective devices that influence the
power delivered to the load.

Many of the modern Icom HF radios control:
- 'maximum output power' using either the forward output of a directional
coupler or a non directional sample of output;
- VSWR protection to limit maximum reflected power indicated by the
directional coupler, typically to a value that is equivalent to the
reflected power at rated output and specified maximum VSWR (eg 11W for a
transmitter rated at 100W and max VSWR=2:1);
- maximum collector current.

The actual power delivered to a severely mismatched load is affected by
all of these. It is likely for such a radio that with a 5 ohm load, the
radio will level 'reflected' power to 11W, 'forward' power would be
16.5W, output power would be 5.5W.

Depending on the way in which maximum output power is detected /
controlled, it is indeed possible to get more than rated output power, so
mismatch doesn't necessarily result in lower radiated power (despite
popular opinion).

Not really - a helix can slow down a wave by
a factor of 50 or more. Approximately a foot and
a half of 75m Texas Bugcatcher stock will be self-
resonant at 4 MHz. That's 90 degrees of antenna
stuffed into about a foot and a half of coil.
90 degrees at 4 MHz is 61.5 feet. The VF of that
coil is 1.5/61.5 = 0.024. Actually, pretty simple.

Talking of 144Mhz (the context of the original posting)...

Competition means that all these guys claim similar SSB telephony sensitivity (measured in a shielded room) which corresponds to an equivalent noise temperature of about 600K.

A key issue is that on a real antenna, this 600K could easily be 6000K due to noise created by IMD in the receiver, and that doesn't show up on the spec sheets, you can only assess that in situ, and it varies from receiver to receiver and antenna to antenna. (The same issue exists with any preamp or LNA.)

Carrying on with the (slightly unrealistic) best case of a 600K receiver, used without a preamp and with say 1dB of line loss, your receiver equivalent noise temperature is nudging 700K which is probably adequate unless you are in the quietest of locations.

What 'works' for someone else isn't guaranteed to 'work' the same for everyone.

An interesting illustration was the case of one of my VHF neighbours who had a narrow filter (of the type used in two way radio duplexors) installed between his preamp and transceiver. I asked why that configuration and the answer was to minimise the loss in front of the preamp (0.5dB of filter loss would add 35K to the system noise temperature). On my suggestion, he moved it in front of the preamp and compared the difference in S/N on a beacon and it was noticeably better in front of the preamp, so despite the additional 35K, it had reduced preamp IMD noise by more than that amount.

You don't make contacts in a shielded room, don't depend entirely on shielded room perspectives for station design.

Egad, here we go again.

Foldback has nothing to do with "reflected power". It's simply that a mismatch results in higher voltage or current at the output which could damage the output device or circuitry. That's why foldback is used.

And, for that matter, "reflected power" isn't radiated *or* absorbed by the transmitter. The transmitter produces power which is sent to the antenna. All the power produced by the transmitter arrives at the antenna less whatever is lost as heat in the transmission line. There are no waves of average power bouncing back and forth on a transmission line. Mathematically separating the power moving down the line into "forward" and "reverse" components doesn't mean that waves of average power actually exist.

If the source is connected to a transmission line, the
mismatch results from a virtual impedance other than the
one for which the transmitter was designed. The virtual
impedance seen by the source is (Vfor+Vref)/(Ifor+Iref)
where Vfor is the forward voltage phasor and Vref is the
reflected voltage phasor. |Vfor|*|Ifor|=Pfor and
|Vref|*|Iref|=Pref If it were not for reflections,
the source would see Z0.

DEVIATIONS AWAY FROM Z0 ARE *CAUSED* BY REFLECTIONS!
Deviations away from the design impedance are what
causes foldback.

> There are no waves of average power bouncing back and forth
> on a transmission line.

One way for that to be true is for reflected energy waves
to contain zero energy but any rational person knows that
cannot be true. Reflected waves consist of an E-field and
an H-field whose ratio is Z0. ExB is watts. Watts are the
unit of power.

Do you really think that the EM waves bouncing back from
your mirror into your eyeballs while you shave contain
ExB = zero watts?

In my experience, I was using a random length long wire antenna using the electrical ground in my home's wiring. In my case I was generating so much RF feedback that it would get back into my switching power supply and cause the OVP SCR to conduct and shut down my whole system. Of course, my radio was part of my antenna system. Then I sank an 8 foot ground rod and connected it to my antenna/tuner/power supply ground and everything changed dramatically. No RF feedback at all that I could discern. My point being that, in my case, I would dispute your statement and say that my ground rod definately was better than an 8 foot radial, counterpoise et al. A good, deep ground rod in reasonably moist soil will turn the ground terminal on your radio into a true zero voltage reference point and stop allowing your antenna and mike/key to function as part of your antenna system. Of course, after I removed the long wire antenna and replaced it with a balanced

antenna, that also worked very well and today I am in a different location with a balanced into and only use my residences grounding system on the second floor, far from the service grounding point. But any time you plan on using "ground" or "earth" as the other half of your antenna, nothing seems to work as well as a good, deeply buried 8 foot ground rod no matter what the purpose; safety, RF etc.. I always thought that the grid grounds and radials were a waste of time. What can make a better ground than earth itself?

A simple proposition for sure... but if it was true, why does the rod need to be 8' long?

The only way that the ground terminal is a 'true zero voltage reference point' wrt the larger ground mass at RF is that if the connection to the ground mass is of zero length, and that isn't true either above or below the ground.

So that it penetrates reasonably deep feet into the earth. Exact length
isn't important but it needs to penetrate a good distance.

With a radial system or mesh system, you are merely fabricating an artifical
counterpoise loosely connected to earth that may give one the perception
that true theoretical 'ground' is achieved, depending of course upon the
frequency in question. A connection to earth mass with a rod that has copper
copper cladding that reacts with the ph of the soil forms an oxide or
hydroxide compound that makes the steel in the ground rod electrically
homogeous with the surrounding soil, rendering the electrical potential of
the steel in the rod at "zero" with respect to RF radiation potentials,
lightening, the power generating generating station or conduction of
electrons in any sense. It is also possible to operate your station at
varying degrees of ground isolation, including a the use of a "virtual"
ground via calculated (and sometimes creative) use of counterpoises but that
does not work very well for most amateurs who use multiple bands, due to the
dependency of the length of the counterpoise(s) on the frequency in
question.

Do you sell copper clad ground rods?

With your creative explanation, you have missed your calling if you don't!

Owen

As a matter of fact, no....i found out when visiting that hardware store
that others had apparently gotten into that business well before me so I
would have a problem with market penetration. But why do you ask?

>

Yeah, that was ugly. I also noticed the author used what appeared to
be a base loaded motorized antenna and then concluded that the
motorized antennas weren't worth a hoot. There are some decent center
loaded ones out there that would have given better results. Base
loaded antennas are probably the worst possible case, based on my
experience. Wonder how that article made it past the editor?

Roy, I have been involved with the evaluation and repair of FM and TV broadcast antenna systems where the initial problem was a failure in the antenna, which then produced a high mismatch between it and the main transmission line.

The allegedly non-existent nodes along the transmission line for this condition did a fine job of melting holes in the inner conductor and Teflon insulators of 3-1/8" OD (and larger) rigid transmission line, at 1/2-wavelength intervals over a considerable length of that line.

What other phenomenon do you believe caused such a result?

But that self-resonant coil is not the electrical equivalent of a 90-degree linear antenna. A coil by itself is not a very efficient producer of EM radiation, whether self-resonant or not.

It depends upon one's definition of "power". A purist
will argue that it is not power until it is dissipated
and steady state reflected power is not dissipated
until power is removed from the source.

The question is: Are the ExB watts associated with a
reflected energy wave defined as "power" or not.

I'm not saying anything about radiation efficiency
just commenting on the phase relationship between
the forward wave and reflected wave.

At the first self-resonant frequency, the feedpoint
impedance is purely resistive indicating that the coil
is indeed electrically 90 degrees long.

Hi Richard

I recognize that you address your question to Roy, so forgive me for
breaking in.
It seems clear that the power is generated at the "source" and disipated
at the "load" and that between the source and the load, only disipative
components will exist.
I would ask "what component along the transmission line between the source
and load can *inrease* power?".

As for the melting of condutors at 1/2 wave intervals, I attribute that to
high current density related to a low impedance at that point. The damage
may actually be related to the high impedance on the line which caused the
voltage to rise too high.

Jerry

Waves of voltage, yes [1].

Waves of current, yes [1].

Waves of average power, no.

History repeats itself in this discussion, so someone is sure to come up with that snappy line about: "Feel the dummy load on the reflected power port of a broadcast TX! If there's no such thing as reflected power, how come that load gets hot?"

That's sloppy thinking. You are not looking directly at the main transmission line - you're looking at the output of a directional coupler that has been <inserted into> that line. Without the coupler, there's nowhere to connect that load.

That coupler is a transducer. It samples signals from the main line, and then it does things to them.

A directional coupler does NOT sample waves of power from the main line. It samples the voltage and current on the main line, adds the reflected components in phase, and delivers them to the output port labeled 'Reflected'. Connect a dummy load there, and sure enough it will get hot... but that's only through the action of the coupler.

The challenge is still on the mat from several previous rounds: can anyone provide a fully detailed description of the operation of a directional coupler, circulator or similar device, based ONLY on waves of forward and reflected power? It can be done easily using forward and reflected waves of voltage and/or current, but that approach is off-limits for this challenge. Believers in waves of power shouldn't need it.

[1] Real hams can blow their own holes in the side of the coax - we don't need no broadcast TX :-)

I know quite a few people that want to try that set up. Without fail,
I warn against it. Some listen, some don't.. But that's ok, sometimes
failure is the best teacher...
Whats really bad is the few die hards that run those and think they
are world beaters. One will tell my friends they are the greatest
thing
since sliced bread, and then I'll have to tell em, no no no...
After a while they don't know who to believe...
So I often have to let them learn the hard way.
I assume the "die hards" don't try anything else to compare with..
I haven't read the article, as I don't QST, but if they recommended
that thing as a good performing antenna, they should be flogged.

We know that helical antennas exist and radiate. The
form factor of a self-resonant 75m bugcatcher coil is
helical and will radiate (even though very inefficiently)
and contacts are more than likely possible. What is your
definition of "antenna"? A self-resonant 75m bugcatcher
coil is not all that different from an Isotron "antenna".

Because that impedance is virtual, it is a *result*
and not a *cause*. The *cause* of the melting is the
in-phase addition of the forward current and reflected
current whose phasor sum is a maximum at points 1/2 WL
apart. Denying that reflected energy exists will not
keep the wire from melting.

The low virtual impedance mentioned above is the
result of:

Z = (Vfor+Vref)/(Ifor+Iref)

at the points where the two voltages are out of phase
and the two currents are in phase.

The sole purpose of a helical (or any other) antenna is to radiate and/or receive EM waves with pattern, polarization and other characteristics suitable for the application.

A bugcatcher coil is not designed to be an antenna, and radiates only incidentally.

ExH = joules/sec = watts. Are watts the the dimensions
of power? Are the E-field and H-field usually given in
RMS (average) values? Can ExH be considered as the
average power in an EM wave? Are you arguing that
watts are not necessarily power? Are you arguing
that it is not power until it is dissipated?

> It can be done easily using forward and
> reflected waves of voltage and/or current, but that approach is

> need it.

"Waves of power" is just a semantic strawman designed
to elicit an emotional response. Anyone using the term
loses technical credibility. It is akin to using the
'N' word to describe race.

How about believers of EM waves containing energy passing
a point? e.g. joules/sec = watts measured at a point?

All this is explained in joules/sec = watts without referring
to volts or amps in my energy analysis article at:

http://www.w5dxp.com/energy.htm

Note that I do not mention "waves of power" anywhere in
my article. What I do talk about is forward energy waves
and reflected energy waves the average value of which can
be measured at a point in joules/sec, i.e. watts.

Maybe you missed what I am saying. Take a 75m bugcatcher
coil and add turns to it until it is self-resonant at
4 MHz. You will have a very inefficient helical antenna.
Radiation from such a helical antenna would be purposeful,
not incidental. Heck, 75m hamsticks are less than 1%
efficient and they still call them "antennas".

What you have learned is that "Ground is NOT Ground, the World Around"
an Old Radiomans adage from an earlier generation. Power Distribution
Ground is not the same as RF Ground, and mostly the two are Mutually
Exclusive.

You ask what makes a better "RF" Ground than earth itself? That is
very simple. Ocean SaltWater makes a much better RF Ground, than
anything you have, or can build, on earth.

Why must you resort to an ad hominem attack
instead of a point by point technical discussion?
What are you afraid might be revealed by such a
technical discussion?

You know and I know that if we polled the readers
of this newsgroup, no one believes in "waves of
average power". Why you guys feel the need to crucify
that old strawman yet one more time just indicates
how devoid your arguments are of any valid technical
content related to reality. Since it allows you guys
to avoid the actual technical issues, the purpose is
obvious: "Since we are such gurus, blindly believe
what we say."

Here are questions for you and the newsgroup:

1. Who believes in "waves of average power"?
Please don't be shy.

2. Who believes that reflected waves do not
exist?

3. If reflected waves exist, who believes they
can actually exist if they are devoid of joules/sec,
i.e. ExH = zero?

It worked. I like the word power. Ronald W.P. King uses it in "Transmission Lines, Antennas and Wave Guides" on page 245 for example:
"Important properties of transmission circuits (wave guides) of all types include the following:
1. Low power loss (a) due to heating the conductors and dielectrics of the circuit itself, and (b) due to radiation.
2. Sufficient power capacity. This implies sufficient spacing of conductors and adequate dielectric strength of insulating media to prevent spark discharge; it presupposes conductors with enough surface to carry large high-frequency currents.
3. An adequate frequency range and a useful frequency response.
4. Physical availability.
5. Special features such as rotational symmetry for swivel points, invariance in polarization of flexible construction."

Mostly Bruce is right. But, I`ve worked in many broadcast plants and can assure you that the radial grounding system is more than adequate as a power distribution ground except for code compliance which may require a ground rod and/or connection to a metallic water pipe. The radials are the best RF ground.

>
> It worked. I like the word power.

Richard, what would be the dimensions of flowing power?
Wouldn't power flowing past a point be watts/sec or
joules/sec/sec? Have you ever heard of such?

Wave energy flows. The power in the wave is measured at
a fixed point, i.e. the measurement point is NOT moving.

A Bird wattmeter is indirectly measuring the power in joules/sec
at a fixed point on the transmission line. The joules are flowing
past a fixed point but the joules/sec power exists at the
measurement point which is NOT moving.

Reflected energy is the energy flowing in the reflected wave.
Reflected power is a measure of that energy flowing past a
fixed point, i.e. the power itself is NOT moving.

"Waves of Average Power" is an oxymoron since waves move
and power doesn't. Be aware that "Waves of Average Power"
is an expression designed to sucker the unsuspected into
a losing argument.

> What other phenomenon do you believe caused such a result?

Let's suppose for a moment that the holes were melted by reflecting waves of average power. Why do they repeat every half wavelength? Do the waves of average power have a phase angle such that they reinforce periodically? As an engineer, you of course know that the average of a periodic function is the integral of that function taken over one period, divided by the period. How then can average power have a phase angle? Or do the waves not have a phase angle but rather change amplitude as they travel? If so, what is the mechanism by which they do? Can you write the equations showing the power at each point along the line and how it can be greater at half wavelength intervals?

In contrast, the existence of traveling and standing waves of voltage and current have long been established. You can find a rigorous analysis of their behavior in a vast number of textbooks. Given the load and transmission line impedances, you can very quickly calculate, even by hand and without the use of a computer, the current and voltage at any point along the line. Unless the line is perfectly matched, there will be repeating points of high current and of high voltage. Depending on the nature of the conductor and insulator, either or both of these can cause localized heating. In the example you gave, the damage is almost certainly caused by high current rather than high voltage. If you'll provide me with the impedance of the load and the impedance and velocity

factor of the cable, I'll show that the high current points fall at the points where the damage occurred. If you tell me the transmitter power output, I'll also tell you what the current was at those points. Can you do the same for your theory of power nodes resulting from bouncing waves of average power? Anyone else having a basic understanding of transmission line operation can explain your cable damage without any necessity to imagine bouncing waves of average power.

If you insist on believing that the damage was caused by traveling waves of average power, please provide an explanation of how these waves interact to create more power at some points than others. Because power is the rate of transfer or dissipation of energy, the power into any point has to equal the sum of the power dissipated at that point and the power leaving that point, unless that point contains some mechanism to store energy. Your analysis has to be consistent with this in order to avoid violating the law of conservation of energy.

I can provide a detailed mathematical quantitative analysis of the nature of traveling voltage and current waves which explain the phenomenon you cite. I'm looking forward to your corresponding mathematical explanation of the phenomenon using traveling average power waves.

Cecil,

If you ever come to the realization that there is a difference between transient conditions and steady-state conditions, along with the realization that standing waves are actually useful, then all of this mumbo-jumbo about energy coursing back and forth along the entire transmission line would disappear.

No waves of power needed, average or not.

Source record: 34994

QST editors can't be expected to be experts on all the topics they have to deal with. Over the years, they've dealt with the problem in various ways. One was to establish a pool of "Technical Advisors" -- volunteers who had particular expertise in various areas. Some manuscripts being considered for publication were sent to the appropriate TAs for comments and review. This practice slowly died out, but I don't know why. I suspect it was because the editors seldom had the time for this step in the process due to erratic scheduling.

Eventually, they adopted a solution which was easy on the editors and their schedules: post the proposed articles to a restricted web site where the TAs could review them and leave comments. This saved the time of communicating with individual TAs, and made it unnecessary to wait for a response -- if comments weren't there by the deadline, too bad. What I saw as one problem with this approach was that comments and analyses were regularly being made by TAs whose appointments had nothing at all to do with the subject matter. As an example (not representing any actual particular occurrence), a TA whose expertise was, say, legal matters or publicity would review (for technical content) an article on phased arrays. As far as I could tell, their reviews were weighted equally to those from people who really understood the topic. In any case, the one or few reviews from knowledgeable people were generally lost in the noise. I don't know if this is the method still being used -- I resigned my TA appointment several years ago when it became apparent that I was no longer able to make any substantial contribution. I know of at least a couple of very knowledgeable people who have done likewise. This is a shame, because they're perfectly willing to provide free technical assistance, yet the ARRL doesn't seem able to find a way to take advantage of it.

I'm not sure they've ever solved the problem of editors who don't understand the material modifying it in such a way as to make it no longer true. In all cases but one when this happened to me, I was able to correct the problems before publication. In one case, however, I wasn't given enough time to correct the numerous misinterpretations, invalid "explanations", and other seriously wrong modifications made by the editor and had to pull the article(*). Several extremely capable people I know, however, have had serious errors introduced to their articles by the editor *after their final review*, so they didn't even get to see the errors until the article was published under their name. Most of these people will never write for QST again as a result. This is one of the reasons that QST has a smaller pool of knowledgeable and capable authors to draw from.

So when you see a technically weak article in QST, the author might not be entirely at fault.

(*) I want to make it clear that I'm very aware that my writing and communicating skills aren't all that great, and I really appreciate having an editor improve the style, clarity, and brevity of my writing, as well as questioning any weak or inconsistent arguments I've made. [A good editor would have cut half the words from the preceding sentence, and made it a lot clearer at the same time.] So I welcome editing. What I do object to is editing which changes the core meaning of the content and/or results in its being technically incorrect.

i.e. without joules/sec passing a point.

> No waves of power needed, average or not.

Please stop doing that, Gene. You know that I don't believe
in "power waves". What you are trying to deny is that EM
waves contain energy that can be measured at a point in
joules/sec = watts. That argument just won't fly.

Here's a physical analogy. We light a butane lighter at one
point and observe the flame. We close the lighter and move
to another point 100 yards away. We light the lighter again
and observe the flame. Did me move the flame by 100 yards?
Or did we convert energy into power at one point, then
move the energy source to another point and convert the
energy into power?

If you move watts of power then you should be able to
measure that movement in watts/sec or joules/sec/sec.
Have you ever measured such?

Cecil,

I did not say anything that denied that EM waves contain energy.

Where this entire controversy always gets hung up is the difference between the traveling wave model where the waves go back and forth over the entire length of the transmission line, and the standing wave model. In the traveling wave model it is necessary for the wave energy to traverse back and forth along the entire line. This leads to the condition where energy is flowing in both directions at the same time at any given point in the line. In the standing wave model the energy simply sloshes back and forth within a single half-wave loop. No energy collisions; no problems at all.

As I have said many times, these are mathematical representations, not physical "reality". Neither is more correct than the other. No physical measurement can tell the difference. But it is often useful to use the most convenient model that does not carry unwanted artifacts and other baggage.

Oh, by the way, it is not possible to measure energy at a point. Energy has an extrinsic, not intrinsic, character. It would be educational to read any good physics text to understand what energy really means and how conservation of energy laws are constructed.

73,
Gene

No, it wasn't quite that bad. The author though seems to have used a tuner to match to the antennas being tested and then coming to some conclusion about how well said antenna radiated energy to a relatively nearby field strength meter (360 feet). One basic problem is that you then end up with some signal level which may or may not be equal to the original output from the rig (apparently an ICOM 706-MKIIG) reaching the antenna. That might make the rig happy but it does leave the antenna with an awfully funny feed at times, one that could be oh 3 dB or so down from what the rig puts out.

How can the input power be the same if it's going through the tuner? The input power is the same at the input of the tuner, but we have absolutely no idea what the output power from the tuner is. Isn't that a problem for a fair test? Would not a more reasonable approach be to use something like Wattmeter and get the antenna resonant? I've seen folks who used antenna tuners find out the tuner can get really hot into some loads? If the tuner is consuming some of the RF as heat, that's power not reaching the antenna ergo not a fair test.

> No problem with 360 feet. Received carrier power is proportional to

Isn't 360 feet within the near RF field at most HF frequencies?

Roy,

If a transmitter produces r-f power, and a load connected to that transmitter via a transmission line dissipates any of that r-f power, then would you not agree that such an r-f transmission line conducts at least whatever r-f power is dissipated by that load?

And if such a transmission line can conduct power in one direction (incident), it can also conduct power equally well in the opposite direction (reflected), until the net result of incident + reflected causes line failure.

When the Zo of a transmission line matches the Zo of a load at its far end, then that far-end Z absorbs nearly 100% of the power delivered there by that transmission line.

If those impedances are not matched, a reflection is generated that may lead to the real-world, destructive and periodic effects on the transmission line that I reported from personal experience, earlier in this thread.

Of course.

> And if such a transmission line can conduct power in one direction

No.

> When the Zo of a transmission line matches the Zo of a load at its far end,
> then that far-end Z absorbs nearly 100% of the power delivered there by that
> transmission line.

This occurs whether or not there's an impedance match. If I connect my transmitter to a 50 ohm dummy load via a half wavelength 300 ohm line, all the transmitter's power (less the line loss) is conveyed via the transmission line to the load. This is in spite of a 6:1 mismatch at the load.

> If those impedances are not matched, a reflection is generated that may lead
> to the real-world, destructive and periodic effects on the transmission line
> that I reported from personal experience, earlier in this thread.

In my example, as at any time the load and line aren't matched, there will be standing waves of voltage and current on the line, which can lead to line failure. In the example you gave, it was almost certainly the high current points which caused it. If you'll pick up any transmission line text, you'll be able to quickly see exactly what happened.

You still haven't explained how these imagined power waves cause periodic effects. Please re-read my last posting -- is it some kind of phase angle associated with the power waves, or is there some mechanism by which they vary with position along the line? I'm looking forward to your mathematical description of what you think is happening. You can

find mine in any textbook on transmission lines. If you'd like, I can recommend a half dozen or more.

Yes, radials simulate a true earth ground by empirical test. They are an excellent counterpoise...the best. But by definition, they are not earth ground.

I haven't read the article, but are different mobile antennas being compared on different vehicles, or the same vehicle? It's amazing how many people don't realize that the vehicle is fully half the antenna, and may in many cases play a more important role in determining overall radiating efficiency than the supposed "antenna". So it's impossible to draw any conclusions about mobile antennas based on comparisons done when they're mounted on different vehicles. It's as much a test of the vehicle's effectiveness as a radiator as it is the antenna's.

Jim,

whatever the in and outs as discussed in this thread, if you cut and resonate at 28.4, have the dipole at a decent height, feed it with 50 ohm coax you should get better than 2:1. Do you know what the actual resonant frequency of the dipole + feeder is?

As an example I have a ten metre dipole in my loft, some 25 feet above ground. It resonates at 28.44 at the end of approx 10 metres of 50 ohm coax, the SWR is 1.4:1 . The bandwidth at 2:1 is 28.25 -28.63. At 2.5:1 it is 28.160-28.760. This is before the ATU, after the ATU the TX sees from 1:1 to 1.4:1 over the whole of ten metres. See http://www.radiowymsey.org/FanDipole/FanDipole.html

Thanks but in regards to radio I don't really go in for belief. I realise that you and one or two others have a faith based approach to antennas but I prefer to make them, measure them and then work with them.

Thanks though :)

I'm using Thunderbird 2.0.0.6, which defaults to flowed rather than fixed width format. Please see http://kb.mozillazine.org/Fixed_width_messages. When flowed text messages are viewed with Thunderbird (at least with mine), they wrap to the window width. If the flowed format is causing a problem for other readers, please email me. If it is a general problem I can force it to post in fixed line width. But let's take the discussion off line.

That would more more for impedance matching rather than the
loading coil itself. I have no real problem with that. I've often used
simple L network tuners for matching mobile antennas.
The system I have a problem with is using the tuner as the
loading coil itself. It's usually a disaster as far as efficiency.
Maximum current is at the coil, and often that coil will be
surrounded by body metal. Not good.. Poor current distribution
through the whip, and low overall efficiency. Not good..
If they left out bugcatchers in the test, no wonder all those
tuner fed things looked so good... :(
If your antenna acts very "high Q", that's actually good. :)
It means it's probably a pretty decent radiator.
I'd be more worried if it acted overly broadbanded, or low Q.
You won't lose much if you use a tuner for Z matching in your
case.

I may be missing the story...Is he feeding all these whips with the
tuner
alone, with no loading coil, or he feeding coil loaded antennas with
a
tuner for impedance matching?
I got the impression he was using the tuner alone, with no other
loading
coils on the whips.
I have no real problem with using a tuner for impedance matching
as long as it's not the actual loading coil.
I guess without seeing the article, it's hard to tell what his point
is.

Well, you would believe anything.

Some MFJ tuners that have a PEP switch do not read PEP reasonably accurately on speech. Some of them that don't work (eg 949E) have a place on the board for the transistor amplifier that is incorporated in other models, and they can be fixed by adding the 10 cent transistor and one or two other parts... but it is a huge job to get the PCB out of the tuner to do the work.

The 'Average Power' reading might be reasonably accurate on an unmodulated carrier, but it is certainly not on a complex waveform like speech, and is another example of MFJ's labelling. In the so-called 'average power' mode, the circuit is a half wave peak responding RF detector with a short (wrt speech) decay time constant driving a D'Arsonval meter movement which responds to the average current where the current is proportional to square root of power under constant carrier.

The BS in the 'average power' story is revealed by measuring the average power of a Morse transmitter sending continuous dits with 50% duty cycle... the 'average power' reading instruments are unlikely to read 50% of the key down power, and the reading is likely to vary significantly with dit speed.

A similar experiment will reveal the failure of some of the MFJ PEP power meters to correctly indicate PEP on the Morse waveform.

Let me add a little to Owen's excellent explanation.

We can mathematically separate any two currents into a "common mode" (or even mode) current and a "differential mode" (or odd mode) current. If the two currents are equal in magnitude and opposite in direction, the common mode component is zero; if they're equal in magnitude and in the same direction, the differential mode component is zero.

This mathematical trickery is very useful in analyzing transmission lines, because superposition allows us to treat the effects of the two mode currents separately and sum the results. In a transmission line, the differential mode current is sometimes appropriately called the "transmission line" current, and the common mode current the "antenna" current. This is because the differential mode current conforms to all the transmission line rules -- that is, it behaves as though it and it alone is being carried by the transmission line, and its properties can be found by applying normal transmission line equations and analysis. No radiation results from the transmission line currents. (In practice, a very small amount of radiation results from the differential current on a non-coax line, but if it's significant, a poor choice of transmission line was made.) And the common mode current behaves just like any other current on a single conductor (or identical currents on two parallel conductors) - it creates a radiating field. The conductor carrying the current is, by any definition, an antenna. So if we want to eliminate feedline radiation we need to eliminate (or, practically speaking, reduce to a small value) the common mode current.

To do this analysis with a symmetrical line such as twinlead or open wire line, we use the currents on the two conductors as the two currents to separate into common and differential mode components. We can do exactly the same thing with coax, using the current on the inner conductor as one of the currents to be separated, and the vector total current on the inside and outside of the shield to be the other. If we do this, we find that the two types of line behave identically: If the common mode current is zero, the line won't radiate (and can be considered balanced). If it isn't, the line will. Equations and analysis are identical. Either type of line can be balanced or unbalanced.

Coaxial lines do, however, have an interesting characteristic not shared by other kinds -- the differential and common mode components aren't simply a mathematical convenience, but are actually physically separate. If we do the analysis described above, we find that the common mode current equals the current on the outside of the shield and the differential current equals the current on the inside. As Owen pointed out, the differential current is solely on the inside of the shield and

the common mode current solely on the outside. While this makes the
effects of each mode current easier to visualize and sometimes to
measure, the net effects of common mode and differential currents are
exactly the same for coaxial and non-coaxial lines.

You have a point. The wattmeter was on the input to the tuner and we
don`t know what the tuner`s loss is. If the loss is negligible,
everything should be OK, and "the input power was the same on each
antenna."

The problem is that it is impossible for EM waves to
do that. An EM wave flows in one direction until it
encounters a physical impedance discontinuity. It
cannot "slosh back and forth" in reality.

The average power is the joules passing a fixed
point in one second. It is the joules that are
flowing, not the watts.

Source record: 34941

I have two beams I want to install on the same mast. They are, Cushcraft MA5B and an 9 element crossed Tonna.

What is the optimal distance that these antennas should be spaced?

What is the minimum distance apart can they be mounted before they have a negative effect on each other?

Does it matter what beam is mounted on the top?

Does it make any difference how close the beams are mounted to the rotator?

This is the first time that I have put any beams up, so I thought I better get some good advice first.

Thanks

This page will show you how to think about it:
http://www.ifwtech.co.uk/g3sek/stacking/stacking2.htm

You'll see that most of your questions have no definite answers. Very close stacking will cause some degradation in performance - especially for the 2m antenna [1] - but how much degradation depends on the specific antennas, and can only be determined by modelling.

The "optimum" stacking distance will also depend on your priorities between HF and VHF, and on how much degradation in performance you are willing to accept.

There are also mechanical considerations. It might be better to mount the HF minibeam at the very top of the stub mast [2], to put it a larger number of wavelengths above ground; but that will create a lot more bending force than mounting the HF antenna below the VHF one. Again, this is very much your decision.

With winter coming on, I'd suggest that you go for strength over performance, and mount the HF antenna very low on the stub mast. The 2m yagi could then be about 1 metre above it. This may not be completely "optimum", but it stands a better chance of still being there next spring.

[1] Whichever way up you install the two beams, the mast will affect the performance of the vertically polarized part of the 2m crossed yagi, because it's in the same plane as the vertical elements. Even if you mount the crossed yagi at the top of a fibreglass mast, the coax feedlines will have much the same effect. However, if you are only using vertical polarization for semi-local working with good signal/noise

margins, you may decide to accept the reduced performance. Most people do, or aren't even aware of it.

[2] Since you are posting from the UK to an international newsgroup, we'd better be aware of a US/UK language difference. In the USA, the "mast" usually means only the tube above the rotator, and people may be assuming that of course you'll have a lattice tower :-) In the UK, the word "mast" is often applied to the whole structure (even to a lattice tower) and we usually call the rotating part a "stub mast".

actually, its not measure energy or power, its measuring voltage and current
and presenting you with the result of a calculation that represents power.

no transmission line conducts power. it conducts moving electrons which are
measured as a current or voltage. power is a figment of our mathematics
that has created a convenient way to take the current and/or voltage and/or
impedance (only 2 of the 3 are needed) and convert them to a measure of
energy flow, or power, that happens to be a nice conceptual way to view
things. we could just as well give up all readings of power and state taht
a transmitter produces 1 amp into a 50 ohm load instead of that it produces
50 watts... the former is more descriptive, the latter is simpler for the
non-engineer.

Like I said, it is indirectly measuring power -
by sampling the voltage and current at a fixed
point in a known Z0 environment and performing
some in-phase and out-of-phase phasor additions.

The point is that it is displaying watts at a
fixed point, i.e. average joules flowing past
a fixed point in one second. It is the joules
that are flowing, not the watts.

Sloshing EM energy is only a math shortcut which
violates the laws of physics and exists only in
your mind (and others). Traveling EM waves agree
with the laws of physics and can be observed with
one's own eyes.

When math shortcuts become one's religion, one
has a definite problem.

How about a case of a non-resonant transmission line whose Zo equals the load Z except for a discrete mismatch somewhere in the line? Reflections from that mismatch will be dissipated in the reverse port termination of a circulator installed at the input of the line. Clearly not all of the power available at the output of the circulator arrived at the antenna (less line loss).

Cecil
I don't want to argue the point but as you know
I consider radio radiator to be an electron accellerator
ie a tank circuit using a full wave (slow wave) length
inductance with a very low capacitance (LC ratio).
It is well known that the electron in a accellerator
aproaches the speed of sound.
The cloud of accellerated particles or electrons
in this case is non polarized which allowes for a
tumbling straight line trajectory.
Now some will be angry accusing me of putting out
false information again or flaunting comedic writing again
but I am being serious

Is the above in conflict with your statement?

Best regards
Art Unwin KB9MZ......XG

"Sloshing" EM waves violates the conservation
of momentum principle.

What reverses the momentum of an EM wave at the
point where it starts "sloshing" around when
there is no physical impedance discontinuity?

In terms of optics, how does light energy just
start "sloshing" around in free space when
there is no change in index of refraction in
the medium?

Given Hecht's equation for a light standing wave
in free space, where are the terms that cause
the "sloshing"?

Speed of sound? That's much too fast for free
electrons in a wire conductor.

> Is the above in conflict with your statement?

In DC circuits, electrons flow at speeds that can
be expressed in cm/min. In RF circuits they hardly
have time to move at all in one direction before
they have to start moving in the other direction.

It is the photons released by energy-rich electrons
that flow at the speed of light. The EM wave energy
is associated with those photons.

Free electrons accellerate from the SURFACE of a wire radiator
so are you saying that it produces photons that move at the speed of
light?
If so how is the accelleration vector imparted to the photon that then
gives
it a further increase in accelleration.
I was thinking that the electron travelled in a straight line until
it was able to find a material surface that is willing or able to
accept a free electron before it decays such as a diamagnetic material
I am travelling in murky waters here so any guidance would be helpfull

You never make an OT post about anything - all you do is keep posting this
stupid woger comment!
You are the biggest jerk around!

2828. Dumb antenna height question

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-27 18:01:30 UTC
From: merlin-7 <merlin-7@sc.rr.com>
Message-ID: <47237d87$0$4998$4c368faf@roadrunner.com>
Source record: 34960

I know the 1/4 wave height rule but I am a bit confused so maybe someone can help me out here.

I have been using a parallel, 3 wire, inverted V with its feed point at 40 feet with good results.

I will be changing my home QTH as soon as my current home sells and will need to erect another tower.

My question is, what can I expect to happen if I placed the same antenna with its feed point at 50 feet? 60 feet?

I know what theory says should happen but I do not know anybody that has raised a HF antenna from one height to another (other than going up over 100 feet or more) In my case, I will be lucky if I can get the feed point at 60 -70 feet.

Can someone tell me what happens when a low antenna is raised from 40 feet to 60 feet from personal experience or something similar ?

Including noise levels etc.

Thanks all
Most of what I have learned about antennas has been from reading posts here as I am a self taught ham for the most part. You can only learn so much from books and sometimes, what is supposed to happen in theory and what really happens is two different things.

Thanks again...

But, don't you see? It is not Mark's fault.
Just ask him.
It is Roger's fault.
It is Dloyd's fault.
It is Steve's fault.
It is Delorean's fault.
Heck, it is your fault, too.
Are you beginning to see the pattern here? When Mark behaves stupidly (a daily occurence) it is ALWAYS someone else's fault. He just cannot help himself, don't you see?

But you are right about one thing. He IS the biggest jerk (I have a less kind descriptor) around.

I have 2 80 meter antennas up. On is about 20 feet and the other is around
45 feet. They are supported so they are just about flat tops. Close in ,
out to about 100 miles there does not usually seem to be any differance.
Sometimes the higher antenna is 2 or 3 s-units beter. Someitmes it does not
make much differance depending on where the stations are.

I would say just go as high as you can and don't worry about it.

Certainly if you install a resistor in the line, whether connected to a circulator or not, some of the power leaving the transmitter won't make it to the load. I was assuming when I made my statement that no such objects were placed in the transmission line, and would hope this condition would be obvious to most readers.

What you need is the free demo version of EZNEC, available from
http://eznec.com, or any other of the currently available antenna
modeling programs. It'll answer your questions very clearly.

What happens in practice is what happens in theory. If it doesn't, then
the theory is incorrect, incomplete, or misapplied.

I'm looking at making a parabolic reflector for a wifi link.

I'm trying to work out the distance required between the radiating
element and the reflector.
Should it be an odd number of quarter wavelengths, or an even number?

(An odd number of quarter wavelengths would be required if there is a
180 degree phase change on reflection, and
and even number would b required if there is no phase change).

So... is there a 180 degree phase change at the reflector?

TIA

It is a little different to that, the feed would normally be placed at the focus of the parabola so that rays emanating from the feed travel to the reflector, and are reflected in a parallel beam.

For optimal results, the feed should illuminate only the reflector, and the illumination should be such that the reflected waves have a constant power density over the projected area of the reflector.

It is not a mater of odd or even wavelengths. The antenna needs to be at
the focus of the reflector. The feed needs to be adjusted so it will put
most of the signal on the reflector without too much over spray.

All the above will depend on what the shape of the dish is.

I have a tubular tower, with no way to have a thrust bearing. So, I have the
Hygain TH3 tribander resting right on top of the rotor flange. 6 m beam is 7
feet up from there, and 2 m beam is half way in between. I care more about
6 than I do about 2 meters. I did run an EZNEC simulation of my 6 m beam
with/without an HF beam 7 feet below it; there was no change in performance.

> Should it be an odd number of quarter wavelengths, or an even number?

Here it is, exactly:

f = D-squared divided by 16-times-d,

where f is the focal length of the dish (your "distance between the
radiating element and the reflector"),
D is the dish diameter, and
d is the depth of the dish

Example; If your five foot dish is a foot deep, D-squared is 25 and
16-times-d is 16; Divide 25 by 16 and mount the radiator (or "feed" in dish
parlance) 1.56 feet away, about 1' 6 3/4". The example is a fairly deep
dish; the shallower the dish, the longer the focal length.

See also http://www.satsig.net/focal-length-parabolic-dish.htm but note he
uses letter "c" for the depth.

I don't think there is any real optimal distance within what most can put
us. I tried to look at what was needed vers what I could put up about a
year ago. I did see the url Ian listed. My requirements was to have about
15 feet of mast out the top of the tower that is 57 feet out of the ground..
At the top went a M2 432 beam, about 4 feet below that went a M2 2 meter
beam both beams were on a 15 foot boom, and close to 5 feet under that went
a 5 element 6 meter beam on a 18 foot boom. Just over the top of the tower
was a 3 element triband for 20,15,and 10 meters. All antennas are
horizontal. I am sure this is nowhere near optimal but just the best for
what I had to work with.

> Sal, more more complicated for offset feed... Owen

Yeah, I thought of that and I have no ready backup for offset. I have
played with both kinds and I'm happy that my two offset feed dishes each
came with a feed-mounting arm already in place. ;-)

My two offset feed dishes have the feed 22.5 degrees offset from the
structural centerline of the dish; the angle of peak signal is therefore
22.5 degees off in the other direction. (Avoiding UP, DOWN, LEFT & RIGHT.)
I think that's a standard.

Given that an offset dish is, I think, more properly described as a
parabolic section, rather than a parabola, I would use the edge of the dish

nearer to the feed for the "f" measurement. (This is intuition with no backup. I'm naked here, so don't look.)

Speaking of dishes, I have two, a 7-foot and a 10-foot, to give away. San Diego, California area. So far, no takers as I cast the net ever wider.

When energy is imparted to an electron, if nothing
changed, it would accelerate. But the electron, instead
of accelerating appreciably, gives up the extra energy
in the form of a photon. Quoting Feynman in "QED":

So now, I present you the three basic actions, from which
all the phenomena of light (RF) and electrons arise.
- Action #1: A photon goes from place to place.
- Action #2: An electron goes from place to place.
- Action #3: An electron emits or absorbs a photon.

Electrons have a rest mass and like all other rest masses
not equal to zero cannot travel at the speed of light. The
particle accelerators that accelerate electrons to near the
speed of light require a lot of power.

> If so how is the acceleration vector imparted to the photon that then
> gives it a further increase in acceleration.

Electrons emit photons which are traveling at the speed
of light. Photons can travel at no other speed although
the VF of the medium affects the absolute speed.

> I was thinking that the electron traveled in a straight line until
> it was able to find a material surface that is willing or able to
> accept a free electron before it decays such as a diamagnetic material

At RF frequencies, the movement of electrons is more like
a vibration than like a travel. They are essentially
vibrating within a small volume while absorbing and emitting
photons. And of course, the uncertainty principle applies.

I have to read up on things a bit more because if a free
electron resides on the surface of a radiator and is
blasted off that surface then it has mass.
It then cannot settle until it finds a surface that will accept it

which must be a similar material that it was blasted off from
i.e. one that will accept free electrons.
So frankly I am not educated enough to understand the nature of
photons
unless it consists of a field created by the accelerated particle
thus it would be better for me to retire gracefully.
Appreciated your responses

Think of a photon being emitted instead of an electron.

Can't do that Cecil. I see radiation as an electron being blasted away
from the area that it was at rest with some electrons that are
blasted of but prevented from leaving the immediate vicinity or
equilibrium boundary returning to the host material. I cannot see
what a photon would add to this scenario since the released electrons
have the energy accorded to it by inductive energy instantaneous
energy.
I see no way how to include another energy packet to enhance this
energy exchange
i.e. blast that overcomes the electron inertia such that it escapes

As I stated earlier I am obviously out of my depth by thinking
contrary to those educated in the field
I haven't had a chance to read Feynman as yet unless it is hidden
somewhere on the net. Is it possible he is in error regarding photons
as something separate from electrons in flight?
Best regards

The confusing part to me is that, although photons do not have rest mass, they do have mass. They are particles. As such, RF can be expressed in terms of both waves and particles but it is not useful to try to conceptualize how this works physically. Getting to the title of this thread, "power" is an expression of the work required to move one coulomb (approximately 10E18 distinct electrons) across a potential difference of one volt for 1 second. However, as you say RF power is not about moving electrons, it is about the emission of photons and this must involve the conversion of joules from one type of "work" to another. Perhaps one could say that the average power of the wave is equal to the average power of the moving electrons produced in the radio circuitry multiplied by the radiation efficiency and gain/loss of the antenna but that is a mathematical expression that serves no real purpose in terms of understanding the science. It is this very lack of understanding on my own part that is one reason the study of RF and antennas is interesting to me.

The electron does not get "blasted" away. It merely goes to a higher energy level. Then when it returns to a lower energy level, the difference in energy is emitted as a photon. The electron does not physically separate from the atom of the antenna conductor material and radiate into free space, only the photonic energy is emitted . This all occurs at a frequency that depends on the tuning of the RF circuit. The antenna conductor should be geometrically sized to support the frequency of the emssions for maximum radiation efficiency. Now, since the emission of photons is also an EM wave emission, the energy emitted has both an electrical and magnetic compoment associated with it. The energy has been converted from the "work" to simply move coulombs (electrons) over a potential voltage difference to "work" needed to radiate photons (waves) into free space. Work is work and it remains the same; what the work accomplishes is different. This part I cannot explain very well since I have no idea how RF freqeuncy, or light or other EM waves can be of both a wave nature and particle (photon) nature, but it is, and that is how the energy conversion works. The dual particle natuire and wave nature of RF/light would almost appear to be "faith based" if it weren't for the large body of mathematics and other physics evidence that supports it.

Thanks for the replies.

I agree that the radiating element must be placed at the parabola focus
to give minimal beamwidth, and that this condition is met when the
radiating element is placed at the focus (which is given by D^2/16d).

The point remains that I can still choose the parabola parameters to set
the focal length to whatever is desired.
Should I choose them so that the focal length is an odd or even number
of quarter wavelengths?

What I really had in mind was a uniformly radiating element (ie a simple
whip) with a parabolic reflector behind it, like this:-
(x
reflector radiating element

To get the right-going signal from the reflector in phase with the
right-going signal from the radiating element I need to choose the
reflector distance correctly.

I have a feeling that there WILL be a phase inversion at the reflector
but I'm not certain.

The reason that I think that there might be a phase inversion is that
the (radiator plus reflector) could be considered to be a (radiator and
its image). At the (perfectly conducting) reflector the voltage will be
zero and the current will be infinite, which implies that, at the
reflector, the reflected wave must be phase inverted wrt the radiated wave.

Any thoughts?

Look, I happen to not fully disagree to what you and Cecil are saying.
An electron can be an active part of a substance indynamic form in
orbit around an atom.
You can also have a static form of electron which is at rest.
For radiation I am referring to the dislodfgement of a static
electron.
On the other hand I believe you are referring to a dynamic electron
in

orbit which constitutes part of that of which we see as a mass.

I decided on a more direct aproach by winding a two wavelength slow
wave coil
which with the addition of a variometer will change the inductance to
line up with the 7/4
wavelength base for a standard slow wave which will bring the
inductance and the winding wavelength in unison with the slow current
velocity.
Sounds more complicated than it really is

As a Student of the Art of Amateur Radio with a special fondness for
antennas I found the article useful and interesting. At least as far
as it went!

Last year I purchased a radio especially to go mobile. I have yet to
find an acceptable mobile HF antenna to use on my Chrysler Minivan. I
am beginning to believe that there are no acceptable solutions to the
problem as I define it.

Further, I have concluded that ALL MOBILE HF installations are poor
compared to a dipole five feet off the ground, some are just worse
than others.

The article simply sheds some light on the practical issues one
encounters with popular alternatives.

I think an auto tuner with whatever whip length one can tolerate is
the best one can do with a Chrysler Minivan.

Modeling programs do not consider the radiation from the loading coils
but field measurements do.

Tuner losses can be estimated from the software in the Arrl Antenna
Books.

If you can write a better article for QST, please do so. But please
remember, most of us don't choose the ethical we drive because of its
ability to carry a less bad radio antenna!

Get yourself a copy of AA6GL's "MOBILE.EXE" antenna program and try
various configurations. I'll bet you a (jelly!) donut that your
perception will change.

Hi "a"

Just a thought -- I think you are concerned with the radiation from the illuminator adding to (or canceling) the radiation from the reflector. Normally, the illuminator is designed to establish a pattern that aims only toward the reflector. But, since you dont wish to shape the radiation pattern from the illuminator, you might want to consider that the total pattern from both the illuminator will depend on how big the reflector is (in wavelengths).
If the parabola is large, the half of the illuminator's radiation in the "wrong" direction wont seriously effect the total pattern, and can be ignored. You might assume the radiation from the reflector is concentrated to be within a 20 degree wide sector (20 dB gain antenna). The radiation from the illuminator in that 20 degree sector is so weak that it will not be noticeable.

The fact is - There are many factors that a designer of parabolic antennas considers. Google

Hi Jerry,
Thanks, yes the adding/canceling was what I was trying to address.
I'd Googled on the subject but couldn't find anything that answered that
point. I did come across some interesting sites that described the need
to illuminate the whole of the reflector to make good use of its full
dish size (and hence minimise beamwidth), but I was trying to keep mine
simple.

Treating it simplistically, I guess that, for a given diameter, a deep
parabola (ie the focus well inside the paraboloid) will capture more of
the radiated energy and redirect it in the required direction, than a
shallow parabola would.

I was thinking that I would go for a sheet of aluminium bent into a 2-D
parabola, about 2.5 wavelengths across, giving me a beamwidth of around
0.5 radians Presumably a 2-D parabola would only have gain in 2-D, and
it would be about 2*pi/0.5 = 12, (11dB over a whip).
For a 2.4GHz signal this equates to a parabola 31cm across.

Hi "a"

I saw http://www.nodomainname.co.uk/parabolic/parabolic.htm on Google
and thought it fit your line of interest. It appears that your goals are
realistic and dont require extensive research on the design of parabaloids.
Try Googling again and see if you cant find some data on WiFi, instead of
parabola antenna design. I have seen many WiFi antenna designs that use
kitchen pots and pans as the reflectors.

I dont see anything wrong with that, normalizing the input impedance is
pretty much standard for comparing antennas.

Basically, as you put the antenna higher up you will get more energy at low radiation angles. This might be good, and it might not.

I used to have a Mosley TA33Jr at 38 feet; I then put up a 20 meter dipole at 55 feet. First comparison was with a station about 1000 miles away, broadside to the dipole. He preferred the TA33 by a small amount. Next came a G station some 3000 miles away, who definitely preferred the dipole. Stations in eastern Europe were up to 2 S units better on the dipole.

I can't comment on that as I did not make any measurements without a balun. It was always going to have a balun because I did not want any significant RF coming down the outside of the coax and causing interference.

It would be a simple matter for Jim to make a balun like mine and I imagine he'd get very similar results.

Hi, I am learning about antennas, and and wondering about how antenna
tuners work. I've read you can use anything as an antenna as long as you
have a tuner. Well, If I put up a wire dipole, and then use a tuner,
what is the best length of wire to use? If I use an 80 meter dipole with
a tuner, is that better than using a 10 meter dipole with a tuner?

I'd build a tuned loop, similar to what AM broadcast dx-ers use. A loop is resonated with a capacitor and coupled into the feedline via a pickup loop. The larger the diameter the tuned loop, the more signal you'll capture. By using a loosely-coupled pickup loop of comparatively few turns, you'll preserve the Q of the tuned loop. This worked well for me on 75m... my loop was about 24" diameter & resonated w/ a 2-section 365pF air variable capacitor.
Rather than seeing a peak in response, you'll see deep nulls in 2 directions. Triangulating on the nulls will pinpoint the location(s) of the noise.

I have a good idea of what EZNEC will show.
What I am looking for Is someone that has raised an antenna from one height to one higher, so I know what to expect as far as noise levels, QSM mostly.
I just want to know what to look for when I raise my antenna in an effort to head off any problems.
I have had really good results with my antenna's feed point at 40 feet but its a bit of a cloud warmer. 60 feet high looks a lot better on paper but I do not know what to expect as far as noise.
Balancing my budget is the hardest part.

The higher you go, the more lightning protection you need, plus more guy wires, etc.

I am trying to figure out the best height I can achive within my budget that has the best results.

Hello Art, there are forms of radiation that involves the motion of free electrons. One type is the mu-meson or "cosmic ray" which, by the way, is more of a clump of electrons that travels at a rather high velocity, about 0.9c. There are beta rays (created in the betatron which was invented at my beloved University of Wisconsin). But to make loose electrons travel in free space at any appreciable velocity requires a tremendous amount of energy, certainly not enough provided by your linear amp, which on the other hand does have more than enough energy to create photons that travel at c. Also, electrons travelling as "rays" in free space are neither wavelike nor do they compose the dual electric amd magnetic fields associated with RF. So, with all due respect, I think you should reconsider the model you are using. I do not have all of the answers but suffice it to say that the type of RF we are discussing is comprised of photons, generated by the excitation and deterioration of electrons from higher energy orbitals to lower energy oribitals in the metal atoms of your antenna conductor material.

Modeling programs do indeed include radiation from the loading coils, provided that they're modeled as a wire helix rather than by use of the lumped load object. EZNEC and NEC both have methods of automatically creating a helix, making this process very easy. I believe most other NEC based modeling programs also have this capability.

Cecil,

This entire thread is silly beyond belief. In any case, no matter how irrelevant, there is no problem at all in balancing momentum when there is lots of stuff around. Momentum is a completely useless concept in this example.

But I will declare you to be the winner. 8-)

I honestly did not think of that. I googled for different variations of
"antenna". I found a web site hamuniverse, and found a very good
description of how an antenna tuner works. So a tuner is really there to
protect the transmitter. You still need the wire cut to frequency if you
want to maximize efficiency and minimize the SWR in the wire. Of course
I am generalizing here. I need the arrl antennabook. ;-)

http://www.hamuniverse.com/tuner.html

A little logic should prove that electrons don't
leave the antenna. Assume that electrons radiate
from the antenna. If so, they would have to be
replaced. Replacing electrons would require a
DC current conponent imposed upon the RF. Does a
DC component exist? Don't most transmitters block
DC from reaching the antenna?

> space at any appreciable velocity requires a tremendous amount of energy,

Where is the information that backs that statement as I need to check
that out?
A static particle (an electron) sits on a diagmatic surface with a
chemical stickynes.
All it takes to dislodge that particle from the surface is the amount
of energy
required to lift up one edge where its inertia is overcome. Thus the
energy to
propel that static particle appears to be minimul at best. When the
energy container of
inductance is released instantaneously then the applied voltage is
extremely high
and easily removes the static particle from the surface.
The above is a lot different from removing a dynamic electron in orbit
around a atom
which requires a tremendous force.
Again, please show me where you get your evidence of a "large" amount
of energy.
I would also add that a dynamic electron may well produce protons but
for a
static particle to produce a photon is just not on the cards as it has
minimul
to zero contained energy.

Efficiency can also be maximized by choosing a
near-lossless transmission line. In that case,
SWR doesn't necessarily need to be minimized.

This article describes how to rebuild a matching unit of a Cushcraft R5
vertical -- by --G0WCW

http://www.mrs.bt.co.uk/mrs/r5/

Nice work!
http://www.mrs.bt.co.uk/mrs/r5/DSCN2478.JPG
Enclosure

The box is from maplin, product number YM91Y and is one of their 'IP
enclosure' range. The box is 150 x 110 x 70mm in size (product codes YM91Y -
grey, YM93B - grey with clear lid). Cost is around six UK pounds.

It is physically the same size as the Cushcraft variant, but the PCB has
to be slightly 'nibbled' at the corners to get it to fit inside the newer
box. I'd say the original Cushcraft enclosure isn't that good as they used
steel screws into brass fixings. The screws rust over and then shear off. In
my view, the Maplin IP enclosure is a better solution to outdoor use (IP56
rated).

What it really is is an impedance matching network. You adjust the antenna tuner so that the transmitter sees 50 Ohms. If your SWR meter is calibrated for 50 Ohms, that means an SWR of 1:1 (between the tuner and the radio).

>> You still need the wire cut to frequency if you
>> want to maximize efficiency and minimize the SWR in the wire.
>
> Efficiency can also be maximized by choosing a
> near-lossless transmission line. In that case,
> SWR doesn't necessarily need to be minimized.
> --
You mean the SWR doesn't have to be minimized on the transmission line. If you don't have a tuner and run a 600 Ohm transmission line into the transmitter, it will be happy at an SWR of 12:1 if the impedance the transmitter sees is 50 Ohms. On the other hand, with 600 Ohm line, and an SWR of 1:1 the transmitter will barf.

The longer wire is usually better than the short. Also, the ARRL recommends a length that is not resonant on any band to make the job of the antenna tuner easier. Wires around 100 feet are often used.

Some experiments like the photoelectric effect leads one to conclude that light must be a particle since the intensity of ejected electrons is only dependent on frequency and is completely independent of amplitude. On the other hand it seems that polarization of the same light source can only be explained by a wave characteristic (otherwise one would have to accept that the polarizing material somehow changed the probablility of the particle-photons to not occur in the polarized dimension). I guess you're right; either one of these experiments can mislead the observer as to the true nature of what is being observed. This is where I plateau in terms of physics comprehension; I am not able to tell the difference between a wave and a particle, understanding as well that there may be none.

> 73, Cecil http://www.w5dxp.com

We may be getting confused with nomenclature here.
I think most people have had to brush off from their clothing
electrostatic
particles. So I will call it a static particle without reference to an
electron.
That static particle can rest on a diagmatic material asd copper and
aluminum,
gold, silver etc is in that class. It is also this class of material
that
is used for antennas no less!
So static particles are allowed to rest on an antenna.
Now a antenna is a tank circuit where the distributed constants of
inductance
and capacitance are energy storage containers. Now is that hard to
understand?
And the L,C ratio to each other is very much a constant in antenna
mathematics.
Do we have anything else? Yes we have resistance. All in all just
three
distributed components
With a tank curcuit the energy containers release their energy in
pulsatic
form just like the voltage on the Tesla coil .
In the case of a radiator a spark is not produced as the power goes to
the
capacitor which later on will release its stored power which goes
back to
the inductance.
Now if resistance is not present then we would have a loss less system
right?
Unfortunately there is a litle resistance present but it will act for
some

time in pendulum style using very little energy.
When a pulse of energy is released down stream to the other end any static
particles will be projected away from the surface where it acts as a radio
communication carrier.
So call this static partical at rest on the radiator surface what you want
it certainly does not produce a photon.
As there is no explanation available as to what radiation is I am content to
stay
with what I have deduced from adding a time variAnce to Gauss's static law
encompassed by an arbitary field which conformes with Maxwells laws as used
to determine characteristics of a radiator via computor programs now in existance.
Now getting back to electrons static forms ofcourse, what a coincidence that we
make our antennas od a diagmatic material which by chance or coincidence or
luck of the draw is the only type of material that will allow a accumullation
of static particles upon its surface.
Now there are sonme other materials which will allow a small amount of static
accumulation on the surface such as some types of steel e.t.c which make
poor radiators.
Why? Because they are not fully populated with static particles or what some
call free electons.
Now this explanation fits very well together so I consider it a suitable
explanation of radiation in the absence of any other explanation.
FIND FAULT WITH IT IF YOU CAN AND LET ME KNOW SO I CAN AMMEND IT.
Good luck and best regards
Art Unwin KB9MZ.......xg

I once saw a demonstration that "BIG UGLY" cb antennas, these are approximately 1/8 wl and have a huge loading coil, have more gain than a 1/4 wl radiator. This certaily appeared to be the case when both the antenna being test and the field strength meter's antenna were both the "big ugly" variety and relatively close together(50'). Could this "gain" be a result of magnetic coupling between the coils or was some other trickery being performed.

Couldnt that be considered an oxymoron.

Ooops! I have not used that part of EZNEC yet so I accept I was wrong.
I will have to look a little deeper into why I was convinced that the
radiation from loading coils was not considered.

I still don't find a problem with publishing the article. If nothing
else it has generated discussion.

If Art was correct you could generate RF just by passing DC through a 1
wavelength loop.
Gee wouldnt that make building a transmitter easy.

There are several faults but let me mention just one: You explain that a static charge can exist on an antenna. In fact, that is true, especially in the presence of moving air that tends to add/strip electrons to the surface resulting in a net positive or negative static charge that can even damage your radio in mobile operation if measures are not taken (not sure if + or - but it doesn't make any difference). But all you have been referring to up to now is the electric E-field. What about the magnetic field (H-field) that is also present in the RF wave? With your radiating electrons theory you

attempt to cover the E-field in terms of static charges that are put into motion and projected from the antenna. If so, how does a loop antenna work? Do static magnets exist on the antenna surface also get put into motion and get projected outwards at exact right angles to the electrons? I have to add a smiley to this because I'm sure you know it is quite a preposterous assertion but I am seriously only trying to respectfully question your model. :-)

Well that is easy!
You can't have static magnetic particles resting on a diagmatic
material
since a diagmatic material is absent any form of hysterysis curve and
a static magnet(
what ever that may be) generates a hysterysis curve

I have to add
> a smiley to this because I'm sure you know it is quite a preposterous
> assertion but I am seriously only trying to respectfully question your
> model.

Don't mind the questions but don't write a book on it until you get a
response

Please take note that Maxwells equations verify this model
I suggest you look up in the archives my research on Gauss
since you are new to the group before you next want to invalidate
Maxwell!!

I don't think it matters. The gain signal off the parabolic
reflector will be so very much stronger -- except for a small antenna. Do
you have the gain formulas? http://en.wikipedia.org/wiki/Parabolic_antenna

This is an unusual concern; it's not common practice to
have an "omni" feed for a parabolic.

There's no doubt this was some sort of trickery. I'd bet any amount of money that if properly measured, the loaded 1/8 wave antenna would be shown to have less gain due to lower efficiency. Even moderately accurate antenna gain measurements are much more difficult to make than most people realize, and there are many ways to be fooled. I couldn't begin to list the all ways you could set up a demonstration like that to get whatever result you desired.

ah, this explains a lot... Art is an aetherist... see
http://en.wikipedia.org/wiki/Luminiferous_aether
the mysterious 'static particles' that aren't bound to the material and
carry the electromagnetic energy can only be the aether. since it is well
known how much energy is needed to free an electron from a metalic surface,
and as was pointed out that if it was really electrons that were leaving the
surface it would require a DC component in addition to the RF to replace

them or the antenna would become charged, it must be aether particles that art is talking about. They would satisfy the massless speed of light particles stuck on the surface and other crud that art is dreaming about in his crude attempt to explain electromagnetics.

Yes, and that is a Z0-match to 50 ohms. What happens
at a Z0-match is wave cancellation of reflected waves
through destructive interference which redistributes
the reflected energy back toward the antenna in the
form of constructive interference energy that joins
the forward wave.

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not actually
annihilated, ... All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction of
light."

The reason that the transmitter is protected is that
the Z0-match *causes* that redistribution of the reflected
energy back toward the antenna. Protecting the transmitter
is a side-effect of tuning the entire antenna *system*
to resonance.

When a charged particle encounters an antenna, the
energy is transferred to the conductor causing a
photonic wave that travels at the speed of light
(VF) to the receiver and on to ground (if grounded).
Static charges on grounded conductors are immediately
discharged to ground. Most amateur antennas are
grounded through the transceiver chassis. Some are
not grounded but the theory has to work for the
grounded ones as well.

Most likely trickery but could conceivably be achieved
through phasing of co-linear radiators. The total radiated
power was no doubt less than the 1/4WL but the phasing
might have caused constructive interference in the remaining
RF waves in the direction of the detector. A loaded CB
antenna does not normally require a "huge loading coil"
so it may have been a phase-reversing coil of sorts as
described by Kraus.

How we negotiate the IT services or software licensing related contracts has a significant impact on how IT meets "getting more done with less" expectations set by executive management. How do we plan and carry out such negotiations for success? Is outsourcing such contract negotiations a good option?

The word "believe" seems to have some religious
connotation so please replace "believe" with
the word "support" above. I didn't think anyone
supported the concept of "Waves of average power"
but apparently I was wrong. I personally support
the concept of RF energy waves associated with
ExB RMS watts just as most technical textbooks do.

Get your mind back to the physics mode. Consider the basicvs infolved
with a field
in equilibrium as in Gauss's ,law of statics.
This method to explain things is used by physicists every day
In a short moment in time a DC pilse enters the field which breaks the
internal equilibrium where the boundary has a rapid change in contour
and fractures.
The DC blast removes the surface particles and in this moment where
equilibrium does not exist the static particles are projected beyond
the boundary before the boundary shape
is repaired. Have you got your mind in the thinking mode yet?Now what
does the blast consist of when energy is released nfrom a capacitor
bearing in mind that the capacitor plates are made of a diagmatic
material? Remember that for this method of deduction all "flux" must
pass thru the field so what is it that is stored on the surface plates
on the capacitor? Sice some particles are ejected from the field it
must bve the same type particles that leave a capacitor where some
replace those that are ejected.
Art Unwin KB9MZ....XG

Cecil
The Masters did not have computors so they tried deduction removing
all that did not meet empirical or mathematical tests before they
expoused them to the World.
In this case they meet empirical tests, they meet mathematical tests,
they abide by Maxwells laws and for those who demand more get an
optimiser computor program and without tying it to a planar mode the
antenna program will come back automatically with a non planar mode of
radiator, a radiator of any size or shape or elevation that is in a
state of equilibrium in singular or group form. The Masters found that
when working along side nature you have to walk in natures shoes but
never, never mess with mother nature.
Cecil, people have stopped calling me a blithering idiot! Are they
beginning to think that on this newsgroup I operate under a psuedo
name then who am I? Should we test QST and ask them to publish this
instead of mobile antenna guff? Where is the person who can clinically
disembowel this model and what University does he teach in? Is the
World correct in allowing computors to machinate the numbers
mathematically first and then allowing scientists to collect those
that look O.K. and then play with them, or did the Masters have the
right idea of turning that approach around for gaining advances?
Your friend
Art

2926. Re: Supposed comparison of Mobile HF Antennas in November QST

Very interesting, indeed. This probably accounts for the gradual shift (not for the better) in QST technical articles over a number of years. There seems to be more "publicity oriented" wording than precise technical content compared to twenty or thirty years ago. I had assumed this was an intentional effort to better address new hams, but I see it may have been due to the editing process.

This editing problem is certainly not confined to QST. One of the few things that sends my blood pressure to an astronomical level is for an editor to make changes they do not understand. I depend on various font and indentation settings for much of my material; now and then an editor will decide to "standardize" these and I go completely off the wall. Unfortunately, in many organizations the editors usually have the last shot at material.

ah, a blast removes the particles... you know how much of a 'blast' is
required to create corona on a wire the way you describe? what electric
field strength at the surface of a conductor is required to create that type
of breakdown in air? how much in vaccuum? define your terms and show all
work or you will lose points on the final grade.

what happens if i build a capacitor with ferromagnetic material??? does it
not work? what about if i use paramagnetic material?

A battery, a flyback transformer etc etc
how much in vaccuum?

Does not require a vacuum. Remember the old days of spark plug
transmissions?

define your terms and show all
> work or you will lose points on the final grade.
>
> what happens if i build a capacitor with ferromagnetic material??? does it
> not work?

No

what about if I use paramagnetic material?

Yes

David turn your attention to antenna computor programs
When made they made assumptions which is a no, no with laws.
The same computor program produces verification of the model!
So why not think about whether computor programs are incorrectly based
or Maxwells laws has some errors. Start your investigation from a

rock
hard surface and not sand which has a habit of drifting in time and
determine
or verify again Maxwells laws and computor programming basics.
Is science back to the poll taking days for verification?
Stop floundaring and get down to serious thinking since memorising
stuff is not getting the job done as it did in college.

Static particles are discharged from the antenna, not flowing!
What returns to the scource is the result of resistance
being present

why should i believe you, you just said that a capacitor with iron plates
can't work which is provably wrong. your understanding of computer modeling
of antennas is similarly flawed.

2931. Re: Distance between beams

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-29 16:05:32 UTC
From: Barrett <barrett@blueyounder.co.uk>
Message-ID: <gxnVi.461388$xp6.166077@fe3.news.blueyonder.co.uk>

I have one last question.

I an using a home made tilt over mast made up of aluminium scaffold tube (2" OD heavy duty) and the same tube for the stub mast. I have two heavy duty brackets made up that clamp onto the scaffold tube to hold the rotator and support bearing in place.

What would be a good average distance to have between the brackets that hold the rotator and bearing?

Thanks

David you have now found something to invest in

With the sky rocketing costs of aluminium and copper e.t.c
now is the time to get in on ferrite capacitors.
Now that you have approved of its use for capacitor
you can reap your just rewards

your understanding of computer modeling
> of antennas is similarly flawed.- Hide quoted text -

I just buy the commercial programs on the assumption
they are not selling me junk. If the results are in
accordance with Maxwells laws then that is fineby me.

I've been pleased so far. I worked some CA QSO party from the middle of
PA on 20 meters with it, and all I could hear I could work (100 watts)
Florida, the midwest, and all the typical 20 meter paths from here too.

40 meters received good signal reports. I worked South Carolina, the
Outer Banks, Virginia. Maine Not enough to make a definitive statement,
but it doesn't not work. No QSO's on 80 yet, but the next evening I take
it out, I'm giving it a try.

It is narrow, but that's only been a big problem on 80.

You are getting the use of a _parasitic_ reflector mixed up with what
amounts to a _mirror_ reflector in your case.

It matters _not_ what the distance is from the driven element at the
focus to the surface of the parabolic reflector -- in wavelengths,
inches, centimeters, or furlongs.

What you could do is mount a _parasitic_ reflector outboard of the the
driven element -- and _this_ would be positioned approx 1/4 WL from the
driven element. Tho', how much gain it might add is questionable...

I assume that you are talking about a length of coax that is attached to a free-space antenna. What about the case where the coax shield is grounded at both ends? (make it a non-ideal ground if you like.) Wouldn't this create a ground-loop that will cause some of the signal current to flow through the ground-connection, thus unbalancing the center-conductor/shield current? In this case, the common-mode current isn't necessarily flowing on the outside of the shield. (I am asking a question here).

Also, consider the case at frequencies low enough that skin-effect doesn't apply. Here there is no inside or outside of the coax shield. Still, the magnetic fields caused by imbalance between center-conductor and shield currents are the same, with or without skin effect.

At least these are the thoughts I had while I was discussing the installation of antennas and tuners on boats. There is no end to the controversy surrounding the grounding of radio equipment on a boat. There the antennas are typically end-fed wires (usually part of the rigging), and some combination of radials and seawater connection for the RF counterpoise.

Just what I needed, I had bought two antennas at the Shelby hamfest getting them mostly for tubing and hardware. I may be able to get them on the air. The fiberglass insulators on mine are shot, Im not sure how I will repair them. Im thikinking about cutting back the rotten part and then building it back up with glass cloth and resin.

A tricky part in answering this is determining what you mean by "shield current". There are separate and distinct currents on the inside and outside of the shield. I'll assume that by "shield current" you mean the vector sum of these two currents.

The first part of the answer is that the current on the outside of the inner conductor is always equal to the current on the inside of the shield, and in the opposite direction (that is to say, they comprise a pure differential current), provided that the shield is at least several skin depths thick. This is a consequence of the confinement of the field by the shield, and has nothing to do with what we connect the cable to. Connections only impact the current on the outside.

Now consider what happens when the coax is connected to a free-space dipole, for example. All the current from the center conductor flows into one half the dipole. But the current on the inside of the shield

has two possible paths: to the other half of the dipole or around the end of the shield to the outside of the shield. I won't go into more detail about this, since I've already done so -- you can see what I've written at http://eznec.com/Amateur/Articles/Baluns.pdf.

If you "ground" both ends of the coax, that is, connect them to conductors which provide another path between the two ends, you have a third path the inner shield can follow -- along the "ground" path. So it splits three ways instead of two. If you use a "pigtail" wire for grounding or connecting to the load, it adds inductance to the desired path to the load, which makes the path back along the outside of the coax more desirable, so you end up with more common mode current than you would with a low impedance connection.

> Also, consider the case at frequencies low enough that skin-effect doesn't
> apply. Here there is no inside or outside of the coax shield. Still, the
> magnetic fields caused by imbalance between center-conductor and shield
> currents are the same, with or without skin effect.

I'm not sure I follow this. When the frequency gets low enough that the field can penetrate the shield, the line behaves more like a twinlead line behaves at HF. As I mentioned in my earlier posting, the line can still have common and differential mode currents -- they're just no longer physically separated.

> At least these are the thoughts I had while I was discussing the

Grounding would be much easier to understand if people would realize that calling a conductor or connection "ground" doesn't impart magical qualities. And that currents flow wherever the impedance dictates.

David,
Your questions go on and on as if you have never taken physics!
To get up to speed you need to take some classes and maybe ask
your lecturer some of the questions that you are asking of me.
Until then start a business making ferrite capacitors which you
say work instead of high priced aluminum. Perhaps start an IPO
and get your money up front since you have proof you can make
it work.Why not join your buddy KB9.... and get on his thread
then overnight you will become an expert, relative that is to
those that you join

Correct, except for the part about destructive interference
redistributing reflected energy. Please note the absence of any such
claim in the cited (or any other) reference.

One addendum:
"Therefore, simple diagrams, such as the one illustrated in Figure 1,
should only be considered as tools that assist with the calculation of
light energy traveling in a specific direction."

The same holds true for the simplified explanation provided by the site.

> The reason that the transmitter is protected is that
> the Z0-match *causes* that redistribution of the reflected

More to the point, the Z-match reflects energy back toward the antenna.

Art --

If you believe that either physics or accumulated field experience supports your belief that "efficient" antennas need to be "tank circuits" where "The DC blast removes the surface particles and in this moment where equilibrium does not exist the static particles are projected beyond the boundary before the boundary shape is repaired," etc etc, then please post proven mathematical support for your concepts -- whether your own, or that of others. Your intuition alone is not sufficient.

And if you can't, then would you not agree that you should NOT be posting such concepts as proven reality, whilst abusing others who doubt and/or ask for proof of your concepts, and misleading those who might believe what you post, without proof of its accuracy?

I don't have any idea. I just put my rotator mounting plate where it fit
the bracing in the tower. That put about 5 or 6 feet of a 21 foot piece of
2 inch OD (1 1/2 trade size of galvinised pipe. I just based that on
where the plate fit and having enough pipe in the tower were I can pull the
rotator out if it needs repair.

again you show your ignorance and try to twist words... i said nothing about 'ferrite' in capacitors, i asked you how to explain why ferromagnetic material as capacitor plates wouldn't work, then asked for the equation reference to show where that effect existed in maxwells laws... which you like to say are correct, but then insist on adding other effects to them that aren't needed nor correct.

While you can not work a station if you can not hear it, that is no way to compair an antenna. I have an off center fed antenna up 45 feet and a tribander up 57 feet. I can hear more on the beam than I can on the OCF . I can probably work all I can hear on either antenna. It is I just hear beter on the beam on the bands it is cut for.

Please note the presence of constructive interference in
the cited reference: "... the photons are redistributed to
regions that permit constructive interference ...", which
implies an equal magnitude of destructive interference
elsewhere in order to avoid violating the conservation of
energy principle. It is akin to the gain of an antenna.
Constructive interference in one direction is matched
by an equal magnitude of destructive interference in
another direction.

> More to the point, the Z-match reflects energy back toward the antenna.

Yes, as "constructive interference" energy which requires
destructive interference elsewhere to balance the
energy equation. Since there are only two directions
available in a transmission line, any constructive
interference toward the load must be balanced by an
equal magnitude of destructive interference toward the
source.

Quoting Reflections II, by Walter Maxwell, page 4-3:
"The destructive wave interference between these two
complementary waves causes a complete cancellation of
energy flow in the direction toward the generator.
Conversely, the constructive wave interference produces
an energy maximum in the direction toward the load,
resulting from the sum of the two reflected waves
and the source wave."

For a non-reflective thin film coating, these two
reflected waves are known as the internal reflection
and the external reflection.

Physical objects redistribute energy. Interference simply describes
its spacial distribution.

>
> It is narrow, but that's only been a big problem on 80.

I've seen some on 80 where the people would tune them
at driving speeds because the leaning back of the antenna
would detune far enough to be a problem. :/
They didn't have a wide enough bandwidth to really get
both positions with a good match. Good performing
antenna though.
How well mine does depends on the path, distance, etc..
On 40m, mine will beat my dipole which is at 35-40 ft
on paths over about 1000 miles or so late at night.
IE: Houston to Florida.
We tested that many times to make sure it was not
a fluke. I have no trouble on 80, but it also varies with
time of day, distance. It's probably at it's worst real early
in the evening to close NVIS range stations. But as it gets
later, it will usually get better and better once the band gets
stable and stretches out a bit. As usual, the longer the path,
the better it might do vs a med height dipole.
But I'm often pretty strong even to NVIS range stations.
Not uncommon to be over S 9.. Sometimes 10-20 over..
Course, all the guys on dipoles might be hitting them at
30-40 over.. :/ But no problem talking. And I've never run
an amp mobile.. Just 100w..

I don't know what kind of pipe it is. I went to a place that sells metal and told them I wanted some galvinised pipe. One piece 1 1/2 inch trade size about 20 feet long and also to support the tower I got 3 pieces that are about 3 or 4 inches in diameter and 9 feet long. Those were for the guy wires. I put around 4 feet of the pipes in the ground and filled them with cement. Hopefully that will keep them from bending over. The tower is guyed around 30 feet and again near the top. It is also in a yard of cement. More or less to Rhon's specs for a 25G tower. I bought the tower sections used. Think it was the least expensive part of the whole thing..

Here are a few pix of the tower.

What are you expecting for birds? Condors?? The old TVRO dishes were for 2-4 ghz I think. If you used it for 10 ghz work it would have incredible gain. The surface would have to be extremely smooth as even minor imperfections woulg be bad for 10 ghz use. I saw an article that a group used a 10' 1nd a 12' dish to go 125 miles over the desert with 802.11b wireless (wireless computer network if you're not a computer person like myself). I have a smaller 4'x6' dish I want to mount on my tower someday so I can screw around on the microwave bands. I live on a mountaintop in Vermont which makes it easier to get out on the upper bands that way. Have fun with it and don't stop dreaming of the possibilities. 73's de KA1LHZ

Jim Kelley wrote:
> Physical objects redistribute energy.

If you consider a Z01 to Z02 impedance discontinuity
to be a "physical object" then I agree.

> Interference simply describes its spacial distribution.

Interference, the noun event, is somewhere in the chain
of *events* between the reflections caused by the impedance
discontinuity and the spacial (re)distribution of energy.
Interference, the noun event, is a subset of superposition,
i.e. not all superposition results in interference.

Interference, the adjective, as in the "interference pattern",
describes the results of interference, the noun event. The
interference pattern describes the spacial distribution.

Maybe your answer to the following question will shed
some light on what you think is our disagreement.

In the RF fields in free space surrounding a dipole,
exactly where are the physical objects that redistribute
the energy? As I understand it, each segment is considered
to be a unit radiator and the radiation interference pattern
is the calculated result of the interference events in free
space in the far field.

Pipe is supplied in various "schedule" sizes, starting at 10. Common iron plumbing pipe is malleable (low carbon steel) and usually Schedule 40. So, what are the actual dimensions? Try here: http://www.engineersedge.com/pipe_schedules.htm. So, commonly available 1-1/2" (1.90" OD) Schedule 40 would have a 0.145" wall thickness.

Art, I am not certain *physically* as to what happens when the RF energy, stored as AC discreet electrons in your tank circuit, is converted to the RF wave/photon energy in the EM wave emitted from your antenna. Maxwell describes "what" happens, not physically "how" it happens. You claim to describe physically "how" it happens and claim that your theory does not disagree with Maxwell. I can say that a supreme being from Xenu causes a rock to fall when I drop it from a cliff and that may not conflict with Newton. But the emission of electrons from any antenna of whatever magnetic properties, assuming it is even a conductor, does not meet basic science unless you are referring to corona which we are not. You have probably read that one can even construct a crude transmitter by rubbing a ping-pong ball on a carpet to induce a static charge on it and then move the resulting E-field it up and down. In that case we have a non-magnetic/non-metallic antenna producing an ELF EM radiowave of about 30 millions meters in wavelength. I do know that EM waves are composed of fields, not discreet electrons moving in space (whether we describe the phenomenon in terms of waves or photons). In response to your post, Maxwells equations are all about *fields*. These EM fields move at the speed of light. Electrons do not move at c. They cannot; it is physically impossible as you know. The electrons involved in creating the EM field are hardly even displaced along the length/surface of your antenna. I submit that, when your equipment generates an EM wave, the finite number of electrons that your tank circuit can hold, although extremely high, can in no way begin to approach the infinite number of receiving "antennas" (much less the number of "electrons" they could each "receive") in the whole universe that can and do receive your signal.

It is Schedule 40 pipe..This is not the best pipe to use, but should be strong enough for me. The tribander is just over the top of the tower and I doubt the other antennas will have much wind load. I live in the middle of North Carolina so we do not usually get much ice or very high winds.

You have said a lot but it appears that for what ever reason you
reject what I submit.
So I give you one morsel to ponder upon. When you apply a time vary
field to a gaussian

static field the result is an equation that matches Maxwell(read
archives for the discussion on that)
Since static particles are in no way in planar form but it still
conforms to Maxwell
one should be able to insert into a antenna computor program with an
optimiser a radiator of some length
at an angle to the earths surface and ask for max vertical or
horizontal gain.
I did that and gave the optimizer response to this group for
verification by any computor program
they want to use. It was verified using NEC 4 and is in the archives.
So disregarding any "how radiation works" I will leave you and anybody
else to explain
1 When a time varying field is applied to a static field the resultant
equation is the same as Maxwells
2 when a non planar radiator as in a static field is inserted in a
program based on Maxwell's laws
it produces a result that is not planar and verified by other antenna
programs.
I welcome any response that explains why such a thing could happen
using established theory.
Forget the hand waving and address those two basic statements in a
scietific manner.
For starters, all of this group stated that you cannot add time to
both sides of the static
equation which put them all in opposition to anything that followed,
despite intervention
from a Doctor at MIT showing that I was correct in detailed
mathematical form
Why? Well it is just because.....no reasons given, just
because.
Your move

Nobody asked me, but fooling around with oven magnetrons is potentially life threatening, since they are properly shielded only when installed as designed. What's cookin' might be _you_!

Most in this group know that, so I'm throwing out the caution for the possible newbie. (There was a rumor years ago about a guy who damaged his internal organs trying to use a magnetron as the LO for a homebrew TVRO satellite downconverter. I looked hard and could not find any sustantiation.)

Wow, I do not know why, but I just had a moment of clarity.

That would make a Yagi's behavior somewhat laser like. Photons would excite a Yagi's element which would then eventually emit its own photon. I wonder if the excited photon would be emitted in the same plane as the received one.......Nahhhhh.

Chris

The energized electrons in the driven element emit coherent
photons some of which are absorbed by electrons in the the
parasitic elements. The energized electrons in the parasitic
elements emit more coherent photons, some in phase and some
out of phase with the driven element photons. Coherent photons
interfere destructively in some places and constructively
in other places. The result is the radiation pattern of
the antenna.

Again, I agree. The reason I suggested a "non-ideal ground" was to de-magic it. We do need to recognize some non-zero impedances on the grounds and shields, and their connections, if we are to analyze how the current splits.

The reason for the low-frequency question is that on the boat installations I've been discussing, there are multiple signal sources and some very non-ideal grounds. The signal sources include DC (due to how the electrical equipment is usually wired), and relatively low frequency signals, sometimes carried on cables in very close proximity to the coax. There is also the RF field from the close-in antenna and RF grounding system. I've been stating that the coax shield does *not* provide a magic shield. Your comparison to twinlead at low frequencies (for current, and thus for inductive coupling), confirms what I have been saying. These superimposed low-frequency currents don't affect the RF situation, but they can affect the equipment itself.

Regards,
-Paul (wb6cxc)

Getting back to the original problem.

Most autotuners can't cope with impedances of less than 5 or 6 ohms.
As you are near that limit even a slight increase in antenna height
may facilitate correct tuning.

In order to improve the antenna balance and RX S/N ratio. Put a good
quality ferrite common mode chokes on the Coax and control cables
going into the tuner (I suggest either 50 ferrite beads over the coax
or 10 turns of coax on a ferrite ring as a minimum) If you wish to
earth the coax do it on the transmitter side of the choke. A few turns
of coax will not provide sufficient choking impedance at 3.8MHz.

The purpose of this is to 'float' the tuner above RF earth so that the
output apears to be balanced. By putting the choke on the input side
of the tuner, it is always working at a constant impedance thus
minimising losses.

You mean the ones that have had too much cheap rum? Wait till the next day and ask them when they have a throbbing hangover.

One advantage, at typical ham frequencies, is that you'll have plenty of them, though you may have a hard time distinguishing one from another.

Thinking from my "Imagination", it would be cool to find a way to "pump"
the parasitic element to emit a companion photon much like the one
emitted from a atom in a lasing medium.

They are a lot like physics professors, i.e. hard to
understand? :-)

As far as RF goes, photons from a single source are
considered to be coherent with each other but not
coherent with any other photons. Photons can only
interfere with other photons with which they are
coherent.

For two incoherent light waves, the irradiance equation
is Itotal = I1 + I2, i.e. no interference term. For two
coherent waves, the irradiance equation is
Itotal = I1 + I2 + 2*SQRT(I1*I2)cos(A).
The extra term in the coherent irradiance equation is
the *interference term* where A is the phase angle
between the fields.

Have you figured out where the physical objects
are around a free-space dipole that cause the
radiation interference patterns?

Then you need to change your definitions, John, -I mean that in a
friendly way. 8^)

Too often, too many time, we expect some sort of perfection. It isn't
going to happen. Mobile HF antennas are just not as efficient as a
"good" land based antenna. I'll leave the definition of good up to
everyone, suffice that the mobile antenna isn't as efficient as most.

That being said, you can have a lot of fun on HF mobile and can talk
around the world. Why let the needed compromises keep you from that?

If you are wanting to squeeze the last little bit of efficiency out of
your antenna, I would suggest a mid-loaded antenna with a capacity hat
on top somewhere (some say directly on top, but you'll have to put up
with a lot of wind loading) Use a loading coil that has as high a Q as
you can get, and bond everything you can in the van - doors, hood,
fenders, frame components, engine, radiator, exhaust system - and in
multiple places. You want as much ground plane as possible, even if at
best you don't get much.

> Further, I have concluded that ALL MOBILE HF installations are poor
> compared to a dipole five feet off the ground, some are just worse
> than others.

I don't think that is an exact comparison, but the question is so what?
Get as good as you can afford/want to put in th elabor, and go have fun

I'm driving a Suzuki Vitara -maybe the smallest SUV around. Yet I have an antenna that allows me to have a lot of fun and yes it does get some stares. If I put a football team pennant on it, everyone thinks I'm kewl.

AS for writing an article for QST, I don't think its a bad idea at all to be critical of an article that could have been written better. That I didn't write one does not mean that those who do have free reign to write a poor one if they like.

Its not meant to be a definitive test of the antenna, but I have used
some antennas where that was not the case, Hopefully this is not the
sort of group where one has to take their antenna to a range before they
are allowed to comment on it, good or bad.

I used it, and didn't have trouble making contacts. Others can determine
if it works or not according to their own guidelines.

You didn't answer my simple question on another
thread. The question is: Can interference occur
in free space devoid of any of your required
physical objects?

Example: Given a cubic meter of free space
containing no physical objects. Can interference
occur within that space? Your earlier posting
implied that interference could not occur in
free space devoid of physical objects.

Not from one source of light without any physical objects to act as a reflecting surface.

Can the physical objects be outside of the cubic
meter of space that is under consideration? If so,
I misunderstood your earlier posting. (If you say
"yes" they could be light-years outside the cubic
meter under consideration.)

Generally, never. We had 3 inches of rain last year. Soon though,
Diane Feinstein and Barbara Boxer will introduce punitive legislation
making it more difficult for people to live in (arid regions of)
Southern California - ostensibly to save Snail Darters in the
Sacramento delta. It's a kind of inedible fish I think.

I don't think it matters where it is, or how much space is involved.
For a single source to create an interferernce pattern, there must be
a reflector somewhere. An antenna tuner for example. Interference is
the result of the overlap of waves.

Jim, could a diffractor or refractor provide the physical device that might
lead to interference?

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&rd=1&item=200168425941&ssPageName=STRK:MESE:IT&ih=010

Continuous 3.5-30 MHz, good for Amateur bands and serious SWL.

Rated 300 watts PEP, 150 watts CW, built-in Cross-Needle SWR/Power meter with 0-30 and 0-300 watt scales, measuring Average and Peak Power.

This tuner uses a T-network that is advertised to match 20-2000 ohm loads. Designed for Balanced Lines, it can also be configured for Coax lines and random long wires.

It might not "load the bedsprings," but should make your Xcvr happy in most other situations.

No, I am not certain, and in the interest of learning from you I am
questioning the generality of whether a reflector is the only means of
creating interference from a single source.

I built a J antenna for 2M meters that worked
better than the antenna that was on the radio.
Problem on 2 meters it was kind of clumsy on 70cm maybe it wouldnt be so
bad.
anyway it was a 3/4 wl piece of brazing rod soldered to the centr pin of the
connector and a 1/4wl section soldered to the shield of the connector, rods
were bridged by a couple of small pieces of fiberglass rod I had around.
Before that I had tried the rubber duck antenna , a telescoping antenna, a
telescoping antenna with a tiger tail. Guaging by the number of repeates I
could hit form mty home the j was best but not much better than the
telescoping. Im not sure the tiger tail helped.

General rule: If you are willing to mess with an antenna for long enough to get the VSWR nice and low at some freq, it will probably perform well. http://www.mfjenterprises.com/products.php?prodid=MFJ-842 is a VSWR meter that will help you with that. (http://www.mfjenterprises.com/products.php?prodid=MFJ-864 will do HF, also -- perhaps a better buy than two separate units.) Not everyone likes MFJ.

As to your antenna, what form will it take? How will you use it? Will it mount directly onto the antenna jack on the radio or will it be on the end of a length of coax? Up on a stick? Does it need to be directional, as for service in the far boonies or for a t-hunt?

I have built several 70cm antennas, including two j-poles out of copper pipe. I also built two ground-plane quarter-wave antennas; one was a serious one for hoisting aloft with fishing line. The other one I built directly on/into an old hard-hat as a novelty. I used a BNC panel-mount jack as the basic structure of both of these antennas, with whip and radials sprouting from the jack. I kept messing with the length, angle and shape of the radials until I had a low VSWR. These antennas weren't tested under extreme conditions, but they did a fine job on the local repeaters. (The hard-hat antenna was operated on low power; why risk compounding the existing "drain bamage"?)

If it needs to be super-light for portability, a wire j-pole out of #10 or #12 AWG copper wire would seem workable. Feed it with a short length of coax and you're golden. A j-pole out of TV-twinlead is also a possibility; I've made a few for 2m, encapsulating them in PVC pipe, but never one for 70cm. (I smell a project.) http://cs.yrex.com/ke3fl/prgms/JPOLEFRM.HTM and click j-pole calculations.

Look a some commercial designs and say, "Oh, I can copy that with a stick and some coat hangers." You probably can.

assume f = 14.1 *10E6/sec

photon energy e=hf=6.63*10E-34 j-sec * 14.1 * 10E6 =98.5 *10E -28J

= photon energy for 14.1 MHz.

Thus, however the quanta are being released, each photon at 14.1 MHz is
being imparted 98.5*10E-28J energy. I see no other means this energy can be
imparted other then via electrons (ON AVERAGE) exchanging orbital states in
the antenna copper (etc.) atoms resulting in a release of this total energy
per photon. How can photons otherwise be manufactured by passing an analog
wavelike-field forcing function through another field?

Above you are referring to tight-binding electrons. But
Our RF antennas make use of *free electrons* which are
thought to exist in the outer orbits of conductors.
Instead of changing orbits within a single atom, these
free electrons jump from atom to atom and from groups
of atoms to other groups of atoms. When a free electron
emits a photon, it is not associated with an orbit
change and so is not quantized to any orbit change. The
photon is instead quantized to the frequency of the
energy source and is therefore coherent with that source
which is our RF transmitters.

Do you consider a dipole in free space to be
a "single source"? There is no reflector yet
there is plenty of interference.

The Top Ten Reasons Men Prefer Guns Over Women

#10. You can trade an old 44 for a new 22.

#9. You can keep one gun at home and have another for when you're on the road.

#8. If you admire a friend's gun and tell him so, he will probably let you try it out a few times.

#7. Your primary gun doesn't mind if you keep another gun for a backup.

#6. Your gun will stay with you even if you run out of ammo.

#5. A gun doesn't take up a lot of closet space.

#4. Guns function normally every day of the month.

#3. A gun doesn't ask , "Do these new grips make me look fat?"

#2. A gun doesn't mind if you go to sleep after you use it.

And the #1 reason...

YOU CAN BUY A SILENCER FOR A GUN

"transmitters emit coherent photons "

Sure Cecil.

And the laser pointer I use was a bit less expensive.

MASER: Microwave Amplification by Stimulated Emission of Radiation

"The fundamental physical principle motivating the MASER is the concept of
stimulated emission, first introduced by Einstein in 1917. Before defining
it we look at two related but more familiar phenomena involving the
interplay between matter and radiation, absorption and spontaneous
emission."
http://einstein.stanford.edu/content/faqs/maser.html

"MASER. In each frame, a molecule in the upper level of the MASER transition
(that is, in the high energy, excited state) is indicated by a large red
circle, while one in the lower level (low energy state) is indicated by a
small blue circle. (a) All of the molecules are in the upper state and a
photon of wavelength l (shown in green) is incident from the left. (b) The
photon l stimulates emission from the first molecule, so there are now two
photons of wavelength l, in phase. (c) These photons stimulate emission from
the next two molecules, resulting in four photons of wavelength l. (d) The
process continues with another doubling of the number of photons."

Stimulated Emission of Radiation is a quantum mechanical effect that has
exactly zero to do with HF radio.
For microwaves we use molecules, for light we use atoms.

I made a helical talkie antenna once from a piece of rubber rod, some wire, shrink sleeving and a connector. I don't have any detailed constuction dimensions. But the tuning involved pulling the end of the wire from the shrink sleeving, and snipping off small sections of the wire while measuring field strength. Several iterations were required, but it worked.

3008. question about Yaesu FT-857D

Newsgroup: rec.radio.amateur.antenna
Date: 2007-10-31 17:30:01 UTC
From: Steve <sdaniel13@speakeasy.net>
Message-ID: <1193851801.554148.111740@19g2000hsx.googlegroups.com>
Source record: 34790

I'm a new ham, looking to buy a transceiver that I'll use as a base station. I want something that won't break the bank, but that will give me room in which to "grow" as I upgrade my license. I have my eye on the Yaesu FT-857D right now and it's gotten some good reviews on the web.

I notice that the FT-857D's current consumption is a maximum of 22 amps, but I'm guessing that this is when transmitting with maximum power on HF, correct? For operating on VHF and UHF, would my Astron 20 amp power supply suffice? I can always upgrade power supplies later, if necessary, when I upgrade my license, but I'd like to think that, if I buy the FT-857D now, I won't also have to buy another power supply right away.

Thanks,

Steve

Fair enough, Owen. The easiest way I can think of to demonstate interference of light is with a laser and a pair of narrow, closely spaced slits. A diffration grating is essentially an array of slit-like reflectors that generates a more complex type of interference pattern. You could use one of the internal surfaces of a prism (refractor) as a reflector. Partially reflective beam splitters or mirrors are often used in interfereometers. And there are of course methods by which to create sonic interference. The simplest way is to wire a pair of stereo speakers out of phase and observe the frequency dependent phase cancellation effect by listening to music at

different positions and speaker separations.

There are any number of possible ways to generate interference phenomena, all of which utilize real physical objects to redirect radiation. It is the real physical objects used to create the interference pattern that redirect energy.

If there is no reflector and no splitter to redirect a portion of the ratiated energy, but an interference pattern still results, then there must be more than a single source. It should be fairly obvious that both parts of the antenna must be present in order to generate the dipole-type interference pattern.

You can also use pure refraction--for example through multiple prisms whose output face is not parallel with the input face, to bend the light around as many total degrees as you wish (barring attenuation in the prism). You can also bend the light away, and then back, to get a displacement. But I suppose in all these, the effect depends on waves coming from what appear to be different points in space.

Of course, it does not require coherent sources to see the effects of interference. Interference is an instantaneous effect, and you can take the average over a single cycle to see the power. So even with sources on slightly different frequencies, it's easy to see the pattern. However, with different frequencies, the pattern is ever-changing, repeating when the sources are all back to the starting phase.

As H.A.S. says, "waves of average nausea" or maybe it's becoming intense nausea. Are we sea-sick yet? Or just sick and tired of it.

Cheers,
Tom

Just trying to understand - are you considering the two
sections of dipole to be two separate sources?

True, but it does require coherent waves to accomplish
the permanent wave cancellation described at:

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not actually
annihilated, ... All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction of
light."

This is what happens to the reflected waves at a Z0-match
in a transmission line.

Yes, in the future we should try to better refinine our
generalizations to include any means which can be used to redirect one
or more paths of radiated energy (not including particles with rest
mass greater than zero) in such a way as to be coincident at some
point in space. Lest we allow ourselves to stray too far from it, the
only point attempting to be noticed here is that all such means must
be physical objects and not photons, waves, or interference patterns
created by any or all the above. Disclaimer: This is neither a new
nor a unique concept.

A dipole is by no means a single (point) source. Each tiny part of the dipole creates a field proportional to the current at that tiny part, so in effect it behaves like an infinite number of sources which are spread out in space along the dipole conductors. Interference of all those various fields is what creates the familiar dipole radiation pattern. In fact, moment method antenna analysis programs such as NEC and EZNEC break the antenna into a finite number of segments and calculate the current (magnitude and phase) on each segment. It then calculates the field produced by each segment according to its length, orientation, and current. The sum of the fields is shown as the radiation pattern. This process can be done manually as well.

The hypothetical isotropic radiator is a point source. It has a perfectly spherical pattern because there's no interference.

I think I know what you want me to say, but I need you to go first.
How many sources is a monopole? :-)

Cecil,

The FSU website you like to reference is a perfect example of the
problem Jim is describing.

As shown, the FSU demonstration is physically impossible. There is no
way for two plane waves to be trucking along independently and then
suddenly decide to interfere.

There is basically nothing wrong with the demo as far as it goes; it
nicely shows the effects of combined phase and amplitude on the
resulting wave. However, the demo is not rigorous science or
mathematics. It is not suitable as an authoritative reference.

As many segments as are specified using EZNEC.
Does that help?

They do NOT "truck along and then suddenly decide to interfere". Such nonsense is just a strawman presented for the purpose of obfuscating the technical facts.

The two independent waves are generated at a physical impedance discontinuity, the Z0-match point, and are immediately canceled at that point. The energy in the canceled waves is redistributed in the only other direction possible in a one-dimensional transmission line.

Exactly the same thing happens when the external reflection is canceled by the internal reflection at a non-reflective 1/4WL thin-film coating on glass. Quoting the Melles Groit web page:

"In the absence of absorption or scatter, the principle of conservation of energy indicates all 'lost' reflected intensity will appear as enhanced intensity in the transmitted beam."

i.e. the energy re-reflected at the Z0-match joins the forward wave toward the load. The conservation of energy principle will not allow any other result. Dr. Best's phantom waves continuing to flow toward the source with zero energy is just a wet dream.

==========
That 22 Amperes max is highly likely for more than 100 Watts RF PEP
(Peak Envelope Power) You rarely need that peak current ; the average
current being approx 8 Amperes on transmit (even with audio compression)
If you are worried that your PSU can't handle brief excursions above 20
Amperes , causing your PSU (perhaps) to shut down or the supply voltage
to drop (when your unit has a voltage fold back facility) ,you can
simply put a (sealed)12 v lead acid battery with a capacity of say 10
Amperes*Hours (AH) parallel to the PSU. The battery will then take care
of the peak current.
With a battery of say 18AH (golf trolley variety) your power supply
unit (PSU) won't need a capacity higher than 8-10 Amperes since the
battery will supply the higher current.
On receive the current will be approx 2 Amperes ,with the PSU having
sufficient excess capacity to charge the battery .
